## RED COD (RCO)

(Pseudophycis bachus) Hoka

## 1. FISHERY SUMMARY

### 1.1 Commercial fisheries

Red cod are targeted primarily by domestic trawlers in the depth range between 30 and 200 m and are also a bycatch of deepwater fisheries off the southeast and southwest coasts of the South Island. The domestic red cod fishery is seasonal, usually beginning in November and continuing to May or June, with peak catches around January and May. During spring and summer, red cod are caught inshore before the fishery moves into deeper water during winter. RCO entered the QMS in 1986.
Reported annual catches by nation from 1970 to 1986-87 are given in Table 1. Foreign vessel catches declined and were negligible by 1987-88.

Table 1: Reported annual catch (t) of red cod by nation from 1970 to 1986-87.

Recent reported landings and TACCs of red cod by Fishstock are shown in Table 2, while Figure 1 depicts historical landings and TACC values for the three main RCO stocks.

Notes:

1. The 1931-1943 years are April-March but from 1944 onwards are calendar years.
2. Data up to 1985 are from fishing returns: Data from 1986 to 1990 are from Quota Management Reports.
3. Data for the period 1931 to 1982 are based on reported landings by harbour and are likely to be underestimated as a result of underreporting and discarding practices. Data includes both foreign and domestic landings. Data were aggregated to FMA using methods and assumptions described by Francis \& Paul (2013).

Table 3: Reported landings (t) of red cod by Fishstock from 1983-84 to 2013-14, and actual TACCs (t) for 1986-87 to 201213. The QMS data is from 1986-present.

*FSU data.
§ Includes landings from unknown areas before 1986-87.
The bulk of reported landings are taken from RCO 3, in particular the Canterbury Bight and Banks Peninsula areas. The red cod fishery is characterised by large variations in catches between years. Research indicates that this interannual variation in catch is due to varied recruitment causing biomass fluctuations rather than a change in catchability. The RCO 3 TACC was reduced by $63 \%$ from the 1 October 2007 to 4600 t , with the TAC being set at 4930 t (customary, recreational and other sources of mortality were allocated 5,95 and 230 t respectively). All RCO stocks fisheries have been put on to Schedule 2 of the Fisheries Act 1996. Schedule 2 allows that for certain "highly variable" stocks, the Total Annual Catch (TAC) can be increased within a fishing season. The base TAC is not changed by this process and the "in-season" TAC reverts to the original level at the end of each season. No RCO stocks have yet had an in-season increase.

Figure 1: Reported commercial landings and TACC for the three main RCO stocks. Top to bottom: RCO2 (Central East), RCO 3 (South East Coast), RCO7 (Challenger).

### 1.2 Recreational fisheries

Recreational fishers take red cod, particularly on the east coast of the South Island. Results of five separate recreational fishing surveys are shown in Table 4.

Table 4: Estimated number and weight of red cod harvested by recreational fishers, by Fishstock and survey. Surveys were carried out in different years in the MAF Fisheries regions: South in 1991-92, Central in 1992-93, North in 1993-94 (Teirney et al. 1997) and nationally in 1996 (Bradford 1998) and 1999-00 (Boyd \& Reilly 2002). Survey harvest is presented as a range to reflect the uncertainty in the estimates.

| Fishstock | Survey | Number | CV \% | Estimated harvest range ( t ) | Estimated point estimate ( t ) 1991-92 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| RCO 3 | South | 104000 | 16 | 90-120 | - |
| RCO 7 | South | 1000 | - | 0-5 | - |
|  |  |  |  |  | 1992-93 |
| RCO 2 | Central | 151000 | 19 | 105-155 | - |
| RCO 7 | Central | 1100 | 34 | 5-15 | - |
| 1993-94 |  |  |  |  |  |
|  |  |  |  |  | 1996 |
| RCO 1 | National | 11000 | 18 | 515 | 11 |
| RCO 2 | National | 88000 | 11 | 80-105 | 92 |
| RCO 3 | National | 99000 | 10 | 90-115 | 103 |
| RCO 7 | National | 38000 | 15 | 30-50 | 40 |
|  |  |  |  |  | 1999-00 |
| RCO 1 | National | 21000 | 36 | 5-11 | 8 |
| RCO 2 | National | 39000 | 25 | 8-14 | 11 |
| RCO 3 | National | 207000 | 25 | 210-349 | 280 |
| RCO 7 | National | 23000 | 50 | 5-14 | 9 |

A key component of the process of estimating recreational harvest from diary surveys is determining the proportion of the population that fish. The Recreational Technical Working Group concluded that the harvest estimates from the diary surveys should be used only with the following qualifications: a) they may be very inaccurate; b) the 1996 and earlier surveys contain a methodological error; and c) the 2000 and 2001 estimates are implausibly high for many important fisheries. The 1999-00 harvest estimates for each Fishstock should be evaluated with reference to the coefficient of variation.

### 1.3 Customary non-commercial fisheries

Quantitative estimates of the current level of customary non-commercial catch are not available.

### 1.4 Illegal catch

Quantitative estimates of the level of illegal catch are not available.

### 1.5 Other sources of mortality

Processing limits on red cod are sometimes imposed to discourage fishers from landing red cod when the species cannot be processed or when markets are poor. This practice has encouraged dumping. Processing limits are currently less of a problem than in earlier years.

## 2. BIOLOGY

Red cod are a fast-growing, short-lived species with few fish in the commercial fishery older than six years. Red cod grow to about 25 cm total length (TL) in the first year, followed by annual growth increments of around 15,10 and 5 cm . Growth of sexes is similar for the first two years, after which females tend to grow faster than males and reach a larger overall length. Sexual maturity ranges from 45 to 55 cm TL with a mean value of 52 cm TL for both sexes at an age of 2-3 years. $M$ has been estimated to equal 0.76 for both sexes. In 1995, ageing of red cod was validated using marginal zone analysis.

In the 1989-90 to 1992-93 fishing years, $80 \%$ of the landings in RCO 3 were $2^{+}$and $3+$ fish ( $50-57 \mathrm{~cm}$

TL). The sex ratio of the commercial catch during this period was skewed towards females during November (F:M ratio of 3.4:1) with the ratio tending to even out by May. Schools are generally comprised of single age cohorts rather than a mix of age classes.

Spawning in red cod varies with latitude, with spawning occurring later at higher latitudes. In the Canterbury Bight, spawning occurs from August to October. No definite spawning grounds have been identified on the southeast coast, but there is some evidence that red cod spawn in deeper water (300-750 $\mathrm{m})$. Running ripe fish were caught on the Puysegur Bank in 600 m during the Southland trawl survey in February 1994. Juvenile red cod are found in offshore waters after the spawning period; however, no nursery grounds are known for this species.

Red cod are seasonally abundant, with schools appearing in the Canterbury Bight and Banks Peninsula area around November. These schools are feeding aggregations and are not found in these waters after about June. Catch data indicates that they move into deeper water after this time. Recruitment is highly variable resulting in large variations in catches between years.

Biological parameters relevant to the stock assessment are shown in Table 5.
Table 5: Estimates of biological parameters for red cod.

| Fishstock <br> 1. Natural mortality ( $M$ ) |  |  |  | Estimate |  |  | Source |

## 3. STOCKS AND AREAS

The number of red cod stocks is unknown. There is no information about stock structure, recruitment patterns, or other biological characteristics that would indicate stock boundaries.

## 4. STOCK ASSESSMENT

No recent stock assessments have been carried out on any red cod stocks. Previous assessments were undertaken, however, these are now outdated.Details appear in previous versions of the Plenary report.

Trawl survey biomass estimates are available from one Tangaroa survey, and five summer and ten winter Kaharoa surveys (Table 6, Figures 2, 3 and 4). In 2001, the Inshore FAWG recommended that the summer east coast South Island trawl survey be discontinued due to the extreme variability in the catchability of the target species. The winter surveys were reinstated in 2007 and this time included additional $10-30 \mathrm{~m}$ strata in an attempt to index elephantfish and red gurnard which were included in the list of target species. Only 2007, 2012, and 2014 surveys provide full coverage of the $10-30 \mathrm{~m}$ depth range. The winter surveys are currently conducted on a biennial cycle.

### 4.1 Biomass estimates

## ECSI

Biomass for red cod from 2007 to 2009 ECSI trawl survey core strata ( $30-400 \mathrm{~m}$ ) was largely unchanged and remained low relative to the period between 1991 and 1994. In contrast the biomass in 2012 was more than six-fold greater than in 2009, followed by a drop of similar magnitude in 2014 (Table 6, Figure 3). The
relatively high biomass in 1994 and the low biomass in 2007-09 are consistent with commercial landings in RCO 3, a fishery in which cyclical fluctuating catches are characteristic. The large biomass in 2012 consisted predominantly of $1+$ year fish. The proportion of pre-recruit biomass varied greatly among surveys ranging from 7 to $59 \%$ of the total biomass and in 2014 it was $49 \%$, reflecting relatively low numbers of adult fish rather than a strong $1+$ cohort. The proportion of juvenile biomass (based on the length-at- $50 \%$ maturity) also varied greatly among surveys, from 27 to $80 \%$, and in 2014 it was $70 \%$ (Figure 4).

The additional red cod biomass captured in the shallow strata ( $10-30 \mathrm{~m}$ ) accounted for only $4 \%$ and $2 \%$ of the biomass in the core plus shallow strata $(10-400 \mathrm{~m})$ for 2007 and 2012 respectively, but in 2014 it was $44 \%$, indicating that in terms of biomass, it is important to monitor the shallow strata for red cod (Table 6, Figure 3). The addition of the $10-30 \mathrm{~m}$ depth range had little effect on the shape of the length frequency distributions in 2007 and 2012, but in in 2014 the largest fish were in $10-30 \mathrm{~m}$ (Beentjes et al. 2015).

The distribution of red cod hot spots within the ECSI survey area varies, but overall this species is consistently well represented over the entire survey area, most commonly from 30 m to about 300 m , but is also found in waters shallower than 30 m .

Red cod

Figure 2: Biomass trends $\pm \mathbf{9 5 \%} \mathbf{C I}$ (estimated from survey CVs assuming a lognormal distribution) and the time series mean (dotted line) from the West Coast South Island trawl survey

RCO

Figure 3: Red cod total biomass and $\mathbf{9 5 \%}$ confidence intervals for the all ECSI winter surveys in core strata ( $\mathbf{3 0} \mathbf{- 4 0 0} \mathbf{~ m}$ ), and core plus shallow strata ( $\mathbf{1 0 - 4 0 0} \mathbf{~ m}$ ) in 2007, 2012, and 2014.

Figure 4: Red cod juvenile and adult biomass for ECSI winter surveys in core strata ( $\mathbf{3 0}-\mathbf{4 0 0} \mathbf{~ m}$ ), where juvenile is below and adult is equal to or above length at which $50 \%$ of fish are mature.

### 4.2 Length frequency distributions

The size distributions of red cod in each of the ten core strata ( $30-400 \mathrm{~m}$ ) ECSI surveys were similar and generally characterised by a $0+$ mode $(10-20 \mathrm{~cm}), 1+$ mode ( $30-40 \mathrm{~cm}$ ), and a less defined right hand tail comprised predominantly of $2+$ and $3+$ fish (Beentjes et al. 2015). The 1996 to 2009 surveys showed poor recruitment of $1+$ fish compared to earlier surveys, whereas the $1+$ cohort was the largest of all ten surveys in 2012 and only average in 2014. Red cod on the ECSI, sampled during these surveys, were generally smaller than those from Southland, suggesting that this area may be an important nursery ground for juvenile red cod. The addition of the $10-30 \mathrm{~m}$ depth range had little effect on the shape of the length frequency distributions in 2007 and 2012, but in in 2014 the largest fish were in 10-30 m (Beentjes et al. 2015).

Table 6: Relative biomass indices (t) and coefficients of variation (CV) for red cod for east coast South Island (ECSI) - summer and winter, west coast South Island (WCSI), and Southland survey areas*. Biomass estimates for ECSI in 1991 have been adjusted to allow for non-sampled strata ( $\mathbf{7} \& 9$ equivalent to current strata 13, 16 and 17). The sum of pre-recruit and recruited biomass values do not always match the total biomass for the earlier surveys because at several stations length frequencies were not measured, affecting the biomass calculations for length intervals. - , not measured; NA, not applicable. Recruited is defined as the size-at-recruitment to the fishery $(\mathbf{4 0} \mathbf{~ c m})$.

| Region | Fishstock | Year | Trip number | Total Biomass estimate | CV (\%) | Total Biomass estimate | CV (\%) | Prerecruit | CV (\%) | Prerecruit | CV (\%) | Recruited | CV (\%) | Recruited | CV (\%) |

*Assuming areal availability, vertical availability and vulnerability equal 1.0. Biomass is only estimated outside 10 m depth except for COM9901 and CMP0001. Note: because trawl survey biomass estimates are indices comparisons between different seasons (e.g., summer and winter ECSI) are not valid

## 5. STATUS OF THE STOCKS

Yearly fluctuations in red cod catch reflect changes in recruitment. Trawl surveys and catch sampling of red cod have shown that the fishery is based almost exclusively on two and three year old fish and is highly dependent on recruitment success.

## RCO 3

| Projections and Prognosis |  |
| :--- | :--- |
| Stock Projections or Prognosis | Biomass estimates from the recently re-instated winter East Coast <br> South Island since 2007 confirm that biomass is low relative to the <br> 1990s. |

## Qualifying Comments

- 

## Fishery Interactions

Red cod are landed as bycatch in barracouta, flatfish, squid and tarakihi bottom trawl fisheries and ling, school shark, spiny dogfish, rig, tarakihi and moki setnet fisheries. Incidental captures of seabirds occur.

## RCO 7

## Stock Structure Assumptions

Stock boundaries are unknown, but for the purpose of this summary RCO 7 is considered to be a single management unit.

| Stock Status |  |
| :--- | :--- |
| Year of Most Recent Assessment | 2009 West Coast South Island trawl survey |
| Reference Points | Target: $M S Y$-compatible proxy based on the West Coast South <br> Island trawl survey (to be determined) <br> Soft Limit: $50 \%$ of target <br> Hard Limit: 25\% of target |
| Status in relation to Target | Unknown |
| Status in relation to Limits | Soft limit: Unknown <br> Hard Limit: Unlikely (< 40\%) to be below |
| Fishery and Stock Trends | Biomass indices have been increasing from a series low in 2000, <br> with the current 2009 index above the long-term mean. |
| Trend in Biomass or Proxy | Unknown |
| Trend in Fishing Mortality or <br> Proxy |  |

Historical survey biomass, Catch and TACC Trajectories

West Coast South Island survey biomass (points) commercial catch (red line) and TACC (blue line) for the period 1990 to 2009. Horizontal line dashed represents the mean biomass index, 1992-2011.

Other Abundance Indices
Trends in Other Relevant Indicator or Variables

Length frequency analysis from the West Coast South Island trawl survey in 2009 show a wide distribution of male fish in 2009.

| Projections and Prognosis |  |
| :--- | :--- |
| Stock Projections or Prognosis | Based on the broad size composition in the survey, high biomass <br> levels are expected to persist in the short-term. |
| Probability of Current Catch / | Soft Limit: Unknown <br> TACC causing decline below <br> Hard Limit: Unknown |

## Fishery Interactions

Red cod are primarily taken in conjunction with the following QMS species: stargazer, red gurnard, tarakihi and various other species in the West Coast South Island target bottom trawl fishery. Smooth skates are caught as a bycatch in this fishery, and the biomass index for smooth skates in the west coast trawl survey has declined substantially since 1997. There may be similar concerns for rough skates but the evidence is less conclusive. Incidental captures of seabirds occur.

Yield estimates, TACCs and reported landings for the 2013-14 fishing year are summarised in Table 7.
Table 7: Summary of yield estimates ( $\mathbf{t}$, TACCs $(\mathbf{t})$ and reported landings $(\mathbf{t})$ of red cod for the most recent fishing year. $M C Y(1)$ from $\mathrm{CY}_{\mathrm{AV}}$ method, $M C Y(2)$ from MIAEL method (range only given).

| Fishstock | FMA |  |  | $M C Y(1)$ | $M C Y(2)$ | 2013-14 <br> Actual TACC | 2013-14 <br> Reported landings |
