

1. FISHERY SUMMARY

1.1 Commercial fisheries

Smooth skate (*Dipturus innominata*, SSK), which are also known as barndoor skates, are fished commercially in close association with rough skates (RSK) in New Zealand. Smooth skates grow considerably larger than rough skates, but both species are landed and processed. Two other species of deepwater skate (*Bathyraja shuntovi* and *Raja hyperborea*) are large enough to be of commercial interest but are relatively uncommon and probably comprise a negligible proportion of the landings.

Skate flesh ammoniates rapidly after death, so the wings are removed at sea, and chilled or frozen. On arrival at the shore factories, the wings are machine-skinned, graded and packed for sale. Most of the product is exported to Europe, especially France and Italy. Skates of all sizes are processed, though some factories impose a minimum weight limit of about 1 kg (200 g per wing), and occasionally wings from very large smooth skates are difficult to market.

Smooth skates occur throughout New Zealand, but are most abundant around the South Island in depths down to 500 m. Most of the catch is taken as bycatch by bottom trawlers, but skates are also taken by longliners. Significant longline bycatch has been reported from the Bounty Plateau in QMA 6. While there is no clear separation of the depth ranges inhabited by rough and smooth skates, smooth skates tend to occur slightly deeper than rough skate (Beentjes & Stevenson 2000, 2001, Stevenson & Hanchet 2000).

Many fishers and processors did not previously distinguish rough and smooth skates in their landing returns, and coded them instead as "skates" (SKA). Because it is impossible to determine the species composition of the catch from landings data prior to introduction of these species into the QMS, all pre-QMS data reported here consist of the sum of the three species codes RSK, SSK and SKA. Landings have been converted from processed weight to whole weight by application of conversion factors.

There have been historical changes to the conversion factors applied to skates by MAF Fisheries and

Ministry of Fisheries. No record seems to have been kept of the conversion factors in use before 1987, so it is not possible to reconstruct the time series of landings data using the currently accepted factors. Consistent and appropriate conversion factors have been applied to skate landings since the end of the 1986–87 fishing year. Before that, it appears that a lower conversion factor was applied, resulting in an underestimation of landed weight by about 20%. No correction has been made for that in this report.

New Zealand annual skate landings, estimated from a variety of sources, are shown in Table 1. No FSU deepwater data were available before 1983, and it is not known whether deepwater catches, including those of foreign fishing vessels, were significant during that period. CELR and CLR data are provided by inshore and deepwater trawlers respectively. "CELR estimated" landings were always less than "CELR landed" landings, because the former include only the top five fish species (by weight) caught by trawlers, whereas the latter include all species landed. As a relatively minor bycatch, skates frequently do not fall into the top five species. The sum of the "CELR landed" and CLR data provides an estimate of the total skate landings. This estimate usually agreed well with LFRR data supplied by fish processors, especially in 1993–94 and 1994–95, but in 1992–93 the difference was 467 t. The "best estimate" of the annual historical landings comes from FSU data up to 1985–86, and LFRR data thereafter.

Table 1: New Zealand skate landings for calendar years 1974–1983, and fishing years (1 October – 30 September)1983–84 to 1995–96. Values in parentheses are based on part of the fishing year only. Landings do notinclude foreign catch before 1983, or unreported discards. FSU = Fisheries Statistics Unit; CELR = Catch,Effort and Landing Return; CLR = Catch Landing Return; LFRR = Licensed Fish Receivers Return;Best Estim. = best available estimate of the annual skate catch; - = no data.

| | | | | | | | | | |

Total skate landings (based on the "best estimate" in Table 1) were negligible up to 1978, presumably because of a lack of suitable markets and the availability of other more abundant and desirable species. Landings then increased linearly to reach nearly 3000 t in 1992–93 and 1993–94, and remained between 2600 and 3100 t until the separation of skate species under the QMS. Reported landings of smooth skate are provided in Table 2.

Smooth (SSK) skates were introduced into the QMS as a separate species from 1 October 2003 with allowances, TACCs and TACs as follow in Table 3. Figure 1 shows the historical landings and TACC values for the main SSK stocks. Owing to problems associated with identification of rough and smooth skates, reported catches of each species are probably not accurate (Beentjes 2005). Initiatives to

improve identification of these species begun in 2003 may have resulted in more accurate data.

Table 2: Reported landings (t) of SKA and SSK by QMA and fishing year, 1996–97 to 2013–14.

*Use of the code SKA ceased once skates were introduced into the QMS in October 2003 and rough skates and smooth skates were recognised as a separate species. From this time all landings of skates have been reported against either the RSK or SSK code.

Table 3: Recreational and customary non-commercial allowances (t), Total Allowable Commercial Catches (TACC,t) and Total Allowable Catch (TAC, t) declared for SSK on introduction into the QMS in October 2003.

| Fishstock | Recreational Allowance | Customary non-commercial Allowance | Other Mortality | TACC | TAC |
|------------------|------------------------|--|--------------------|------|-----|
| SSK 1 (FMAs 1-2) | 1 | 1 | 1 | 37 | 40 |
| SSK 3 (FMAs 3-6) | 1 | 1 | 6 | 579 | 587 |
| SSK 7 | 1 | 1 | 2 | 213 | 217 |
| SSK 8 (FMAs 8-9) | 1 | 1 | 1 | 20 | 23 |
| SSK 10 | 0 | 0 | 0 | 0 | 0 |

1.2 Recreational fisheries

Recreational fishing surveys indicate that skates are very rarely caught by recreational fishers.

1.3 Customary non-commercial fisheries

Quantitative information on the level of customary non-commercial take is not available.

1.4 Illegal catch

Quantitative information on the level of illegal catch is not available.

1.5 Other sources of mortality

Because skates are taken mainly as bycatch of bottom trawl fisheries, historical catches have probably been proportional to the amount of effort in the target trawl fisheries. Past catches were probably higher

than historical landings data suggest because of unrecorded discards and unrecorded foreign catch before 1983.

Figure 1: Reported commercial landings and TACCs for the four main SSK stocks. From top left to bottom right: SSK 1 (Auckland East), SSK 3 (South East Coast, South East Chatham Rise, Sub-Antarctic, Southland), SSK 7 (Challenger), and SSK 8 (Central Egmont, Auckland West).

2. BIOLOGY

Little is known about the reproductive biology of smooth skates. Smooth skates reproduce by laying yolky eggs, enclosed in leathery cases, on the seabed. Two eggs are laid at a time, but the number of eggs laid annually by a female is unknown. A single embryo develops inside each egg case and the young hatch at about 10–15 cm pelvic length (body length excluding the tail) (Francis 1997).

The greatest reported age for smooth skate is 28 years for a 155 cm pelvic length female (Francis et al 2004). Females grow larger than males, and also appear to live longer. There are no apparent differences in growth rate between the sexes. Males reach 50% maturity at about 93 cm and 8 years, and females at 112 cm and 13 years. However, the small sample size of mature animals, particularly females, means that the maturity ogives are poorly defined. The most plausible estimate of M is 0.10–0.20. Biological parameters relevant to stock assessment are shown in Table 4.

Table 4: Estimates of biological parameters for skates.

3. STOCKS AND AREAS

Nothing is known about the stock structure or movement patterns of smooth skates. Smooth skates are distributed throughout most of New Zealand, from the Three Kings Islands to Campbell Island and the Chatham Islands, including the Challenger Plateau, Chatham Rise and Bounty Plateau. Smooth skates have not been recorded from QMA 10.

In this report, smooth skate landings have been presented by QMA. QMAs form appropriate management units in the absence of any information on biological stocks.

4. STOCK ASSESSMENT

4.1 Biomass estimates

Relative biomass estimates are available for smooth skates from a number of trawl survey series (Table 5). Biomass estimates are not provided for surveys of: (a) west coast North Island because of major changes in survey areas and strata during the series; or (b) east Northland, Hauraki Gulf and Bay of Plenty because of the low relative biomass of smooth skates present (usually less than 100 t). In the first survey of each of two series (east coast South Island and Chatham Rise) the two skate species were not (fully) distinguished. Furthermore, there are doubts about the accuracy of species identification in some other earlier surveys (prior to 1996). Consequently, trends in biomass of individual species must be interpreted cautiously. To enable comparison among all surveys within each series, total skate biomass is also reported.

As the catch from the South Island trawl surveys changes without wide inter-annual fluctuations and the CVs are relatively low it appears that they are able to track smooth skate biomass in FMAs 3 and 7, and on the Chatham Rise. West Coast South Island surveys (Figure 2) show that the relative biomass of smooth skate in FMA 7 declined substantially from 1997 to 2009, but appear to have increased in 2011 and 2013. Smooth skate relative biomass on the Chatham Rise increased to 2001, and has declined since then.

The East Coast South Island winter surveys from 1991 to 1996 (30–400 m) were replaced by summer trawl surveys (1996–97 to 2000–01) which also included the 10–30 m depth range; but these were discontinued after the fifth in the annual time series because of the extreme fluctuations in catchability between surveys (Francis et al. 2001). The winter surveys were reinstated in 2007, and this time were expanded to include the 10–30 m depth range, in order to monitor elephantfish and red gurnard. Only 2007, 2012, and 2014 surveys provide full coverage of the 10–30 m depth range.

Smooth skate biomass estimates in the core strata (30–400 m) for the east coast South Island winter trawl surveys in recent years were higher overall than in the 1990s (Figure 3). The additional biomass captured in the 10–30 m depth range was negligible in 2007, 2012 and 2014, indicating that in terms of biomass, only the existing core strata time series in 30–400 m should be monitored. 1180

The smooth skate length distributions for the east coast South Island winter trawl surveys have no clear modes and comprise multiple year classes with the possibility of a juvenile mode centred about 20 cm corresponding to 0+ fish in shallower depths (Beentjes et al. 2015). The rest of the distribution includes multiple year classes from about 1 to 25 years. The 30–100 m strata tend to have more larger skates than the deeper strata. The surveys appears to be monitoring pre-recruited lengths down to 0+ age, but probably not the full extent of the recruited distribution. Length frequency distributions are reasonably consistent among surveys with differences mainly confined to recruitment of the first few year classes. No lengths were measured before 1996. The addition of the 10–30 m depth range has not changed the shape of the length frequency distribution (Beentjes et al. 2015).

Figure 2: Smooth skate biomass ±95% CI (estimated from survey CVs assuming a lognormal distribution) estimated from the Chatham Rise (top) and west coast South Island (bottom) trawl surveys.

Figure 3: Smooth skate total biomass and 95% confidence intervals for the all ECSI winter surveys in core strata (30–400 m), and core plus shallow strata (10–400 m) in 2007, 2012 and 2014.

4.3 Yield estimates and projections

MCY cannot be estimated.

The *MCY* estimator that has the lowest data requirements ($MCY = cY_{AV}$; Method 4), relies on selecting a time period during which there were "no systematic changes in fishing mortality (or fishing effort, if this can be assumed to be proportional to fishing mortality)". This method was not applied because no information is currently available on skate fishing mortality, or on trawl fishing effort in the main skate fishing areas.

CAY cannot be estimated.

4.4 Other factors

Species that constitute a minor bycatch of trawl fisheries are often difficult to manage using TACCs and ITQs. Skates are widely and thinly distributed, and would be difficult for trawlers to avoid after the quota had been caught. A certain level of incidental bycatch is therefore inevitable. However, skates are relatively hardy, and frequently survive being caught in trawls (although mortality would depend on the length of the tow and the weight of fish in the cod end). Skates returned to the sea alive probably have a greater chance of survival than most other fishes.

*Biomass estimates are for core 300–800 m strata only

5. STATUS OF THE STOCKS

No estimates of current or reference biomass are available.

SSK 7 relative biomass estimates from West Coast South Island trawl surveys revealed a strong decline. Although this decline is cause for concern, the reason for the decline is uncertain and requires further investigation.

For all other skate QMAs it is Unknown if recent catch levels or the TACC will cause skate populations to decline. Reported landings and TACCs for the 2013–14 fishing year are summarised in Table 6.

| Table 6: | Summary of | of TACCs (t), and | reported landings (t |) for smooth skates | for the most recent fishing year. |
|----------|------------|-------------------|----------------------|---------------------|-----------------------------------|
| | | | | | |
