ERRATUM

A version of this report was posted on the websites at https://mpi.govt.nz/document-vault/9701 and https://fs.fish.govt.nz/Page.aspx?pk=113&dk=23935 prior to the 24th of November 2015 and was subsequently discovered to contain an error.

This error affected Table 2, Figure 2c and Figure 9 (and accompanying text) and resulted in the overestimation of bycatch. So if this report was accessed from that website prior to the 24th of November 2011 then please replace that with this corrected version.

TABLE OF CONTENTS

EXECUTIVE SUMMARY

Ballara, S.L. (2015). Fish and invertebrate bycatch in New Zealand deepwater fisheries from 1990–91 until 2012–13. ***New Zealand Aquatic Environment and Biodiversity Report No. 158.*** **79 p.**

Commercial catch-effort data and fisheries observer records of catch by species provided by the Ministry for Primary Industries (MPI) were used to estimate the level of individual fish and invertebrate species bycatch in each fishing year from 1990–91 to 2012–13 for the following Tier-1 deepwater fisheries: which included the arrow squid (SQU); hoki/hake ling (HOK/HAK/LIN); southern blue whiting (SBW); jack mackerel (JMA); orange roughy (ORH); oreo (OEO); and scampi (SCI) trawl fisheries, and the Ling (LIN) longline fishery.

The estimation process for the hoki, hake and ling trawl fishery were stratified according to fishery area, and estimates of precision were calculated using bootstrap methods. Bootstrap-based precision estimates were also calculated for the ling longline fishery to 2011–12, and the arrow squid fishery to 2010–11. For the remaining fisheries no stratification was used and no estimates of precision were calculated.

Summary tables were made for each fishery, and for all fisheries combined, to provide an easy reference for the bycatch trend of each species or species group caught in these fisheries. Improvements in species identification, introduction of new codes, and changes in observer recording practices can have an effect on the apparent increase or decrease in the bycatch of certain taxa and should be considered when interpreting trends.

All of the fisheries examined showed measurable declines or increases in bycatch of certain species over time, and consistent declines or increases were seen for a few species across six or more of the eight fisheries. Those increasing were; deepsea skates (*Notoraja* spp.), Baxters lantern dogfish (*Etmopterus baxteri*), pale ghost shark (*Hydrolagus bemisi*), and javelinfish (*Lepidorhynchus denticulatus*). Those declining were; bluenose (*Hyperoglyphe Antarctica*), ghost shark (*Hydrolagus novaezealandiae*), and skates (Rajidae and Arhynchobatidae). Future analyses may include a breakdown of trends by area and fishery within these New Zealand deepwater fisheries. Care in interpretation of slope needs to be taken into account, especially for species with few instances of catch, and some trends are driven by greater specificity in observer reporting over time. Overall fishery bycatch shows different levels of bycatch in different fisheries. The hoki, hake or ling trawl target fishery had the highest bycatch levels from 1997–98 to 2003–04, while fisheries with low bycatch levels included the orange roughy, oreo, and southern blue whiting trawl fisheries, and the ling longline fishery. Coarse estimates and precision estimates (those generated from more detailed information) were similar for most fisheries.

INTRODUCTION

This report was prepared as an output from the Ministry for Primary Industries project DAE2010-02 "Bycatch monitoring and quantification of deepwater stocks" and addresses the following Specific objective for year-4.

4. To provide annual estimates of bycatch for nine Tier-1 species fisheries (SQU, SCI, HAK, HOK, JMA, ORH, OEO, LIN, SBW).

The purpose of this research was to compile a list of all fish and invertebrate bycatch species in New Zealand deepwater fisheries, with estimates of annual catch levels, which could be relatively rapidly produced and regularly updated. This would allow early detection of any downward (or upward) trends in bycatch of individual species in all Tier-1 deepwater fisheries, not just in the single fishery typically examined in any one year. By fine-tuning these estimates for the fishery under closer examination in each year (in this year the hoki, hake, and ling trawl fishery) and providing estimates of precision, an overall picture of the annual bycatch of a large number of species, across each fishery, can be built up over multiple years—with increasing precision in each year.

This report provides the third iteration of this plan, the first two provided fine-tuned estimates for only the arrow squid trawl fishery (Anderson 2013b) and only the arrow squid trawl fishery and ling longline fishery (Anderson 2014a).

METHODS

Observer bycatch data were extracted from the MPI ***cod*** database for each of the Tier-1 species target deepwater fisheries (hoki/hake/ling trawl, jack mackerel trawl, orange roughy trawl, oreo trawl, southern blue whiting trawl, scampi trawl, arrow squid trawl, and ling longline) for the period 1990–91 to 2012–13. These data were subjected to the same error-checking procedures as used for the hoki, hake, and ling trawl fishery by Ballara & O'Driscoll (in press).

The total catch and frequency of capture of each bycatch species was examined in each fishery, and those species for which there was a total of less than 10 kg of observed catch over the entire 23-year period, or which were observed caught on five or fewer occasions, were disregarded. It was considered that either the capture of such species was so rare as to be irrelevant, or the likelihood was high that such records were the result of the species code being incorrectly recorded by the observer. Annual bycatch ratios for the remaining individual QMS and non-QMS species (fish and invertebrates) were then calculated for each fishery.

Commercial catch records were also obtained from the Ministry for Primary Industries for each fishery, groomed according to the procedures described in Ballara & O'Driscoll (in press), then used to calculate annual effort (number of tows or longline sets) for each fishery.

For each fishery the annual species specific bycatch ratios were multiplied by the annual effort in the fishery, without stratification, to produce simple estimates of total annual bycatch without any estimates of precision. An indication of whether the bycatch of each species increased, decreased, or stayed relatively unchanged over time was calculated in the form of a slope coefficient for a loglinear regression fitted to the data, with a significant trend where the absolute value of the slope was less than 0.01. The number of species showing increases or decreases in catch over time for each fishery were noted, as were the number of species showing significant increases or decreases in catch.

For the hoki, hake and ling trawl fishery, the procedure was similar but was extended to include an estimate of precision derived from an area-stratified bootstrapping procedure used for the combined species groups (QMS, non-QMS, and invertebrates) in Ballara & O'Driscoll (in press). This procedure rounds the estimates of total annual catch to the nearest 0.1 t and so species with less than this level of catch in at least one year were excluded. See Ballara & O'Driscoll (in press) for a more detailed description of the general methodology used to extract and groom observer and commercial fishing return data, calculate bycatch ratios and annual levels, and estimate precision. A comparison of coarse and precision slopes for a few selected species in the hoki, hake, and ling trawl fishery were produced for comparison between these methods. The arrow squid trawl fishery precision estimates to 2010–11 Anderson (2013b) and ling longline precision estimates to 2011–12 from Anderson (2014a) were also included.

Tables were constructed for each fishery showing the annual estimated bycatch for each species and the slope coefficient. For all years in the hoki, hake, and ling trawl fishery the CV for each estimate was also provided. A colour-coded summary table is also provided, in order to clearly indicate the species in each fishery with declining or increasing catch levels.

A summary of bycatch in all the reported fisheries by time, and comparison of total bycatch rates across all fisheries was produced.

RESULTS

Annual bycatch estimates for individual species in each of the nine Tier-1 deepwater fisheries are given in Tables 1 to 8. The following is a brief summary of these tables, including figures showing the annual bycatch of the main bycatch species and those with the greatest increase and decrease over time.

Note that in some cases the apparent increase or decrease in bycatch of a species is likely to be due to improvements in species identification, or changes in observer recording practices, over time. For example, in the arrow squid fishery, the increase in bycatch of smooth red swimming crabs (*Nectocarcinus bennetti*) appears to be at the expense of bycatch of the similar-looking paddle crabs (*Ovalipes catharus*), and the increase in bycatch of floppy tubular sponges in the hoki/hake/ling trawl fishery actually reflects the improved identification of sponges in more recent years. Where the possibility of this was strongly suspected in the species figured, it has been noted in the figure captions; for other species, e.g., slender jack mackerel, the changes in bycatch may reflect real changes in species abundance.

Arrow squid trawl fishery

- Of the 185 bycatch species examined, 47 have shown a decrease in catch over time and 138 an increase in catch; with 13 having shown a significant decrease and 18 a significant increase in catch.
- The species showing the greatest decline were paddle crabs (PAD), combined jack mackerel species (JMA, JMM, and JMN) and barracouta (BAR) (Figure 1a).
- The species showing the greatest increase were silver dory (*Cyttus novaezealandiae*, SDO), giant spider crab (*Jacquinotia edwardsii*, GSC), and the smooth red swimming crab (NCB) (Figure 1a).
- The most commonly caught bycatch species were barracouta (*Thyrsites atun*, BAR), silver warehou (*Seriolella punctata*, SWA), and combined jack mackerel species: greenback jack mackerel (*Trachurus declivis*, JMA); slender jack mackerel (*Trachurus murphyi*, JMM) and yellowtail jack mackerel (*Trachurus novaezelandiae,* MN), (Figure 1b). The twelve most common bycatch species are also shown in Figure 1b.

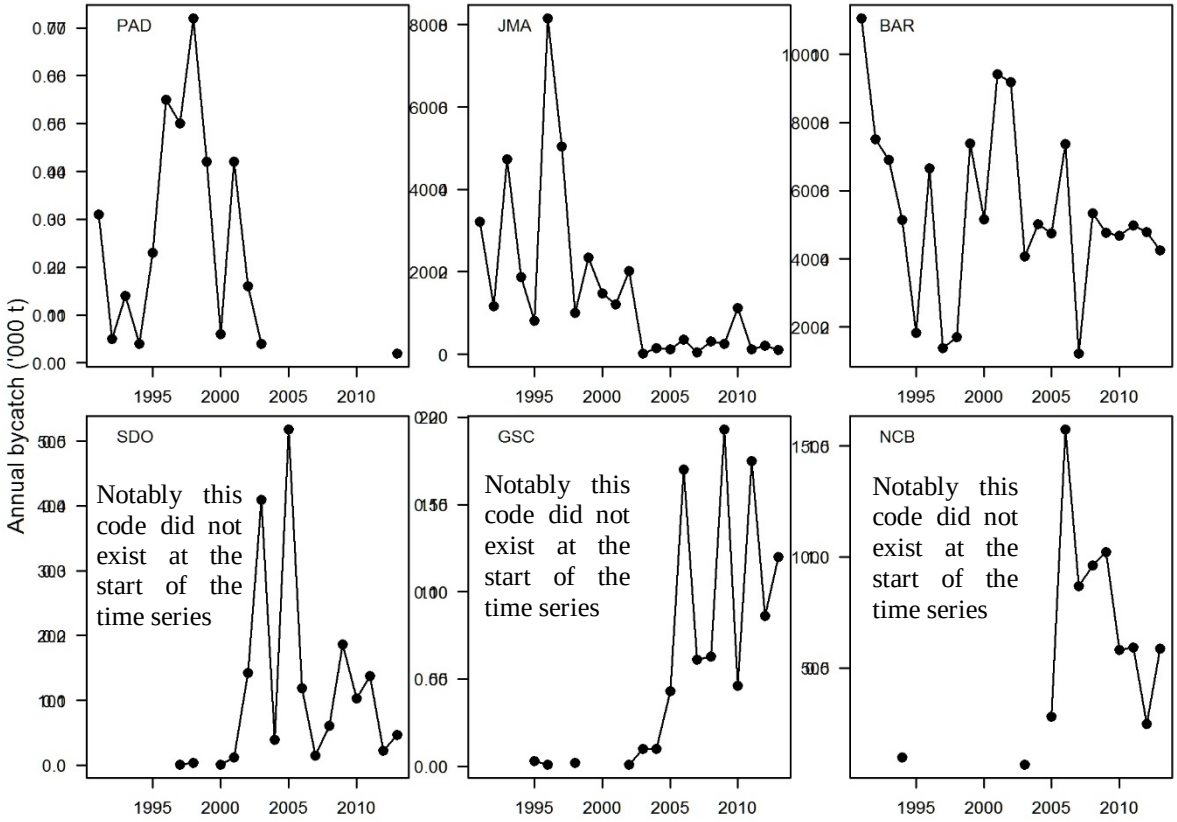

Figure 1a: Annual bycatch estimates in the arrow squid trawl fishery for the species which have shown the greatest decrease (top) and greatest increase (bottom) between 1990–91 and 2012–13. See text above for explanation of the species codes. Note: the scale changes on the y-axis between plots and the increase in PAD and decrease in NCB may be due to NCB being erroneously recorded as PAD before 2003–04. Trends implied by codes which did not exist at the start of the time series are indicated on the graphs.

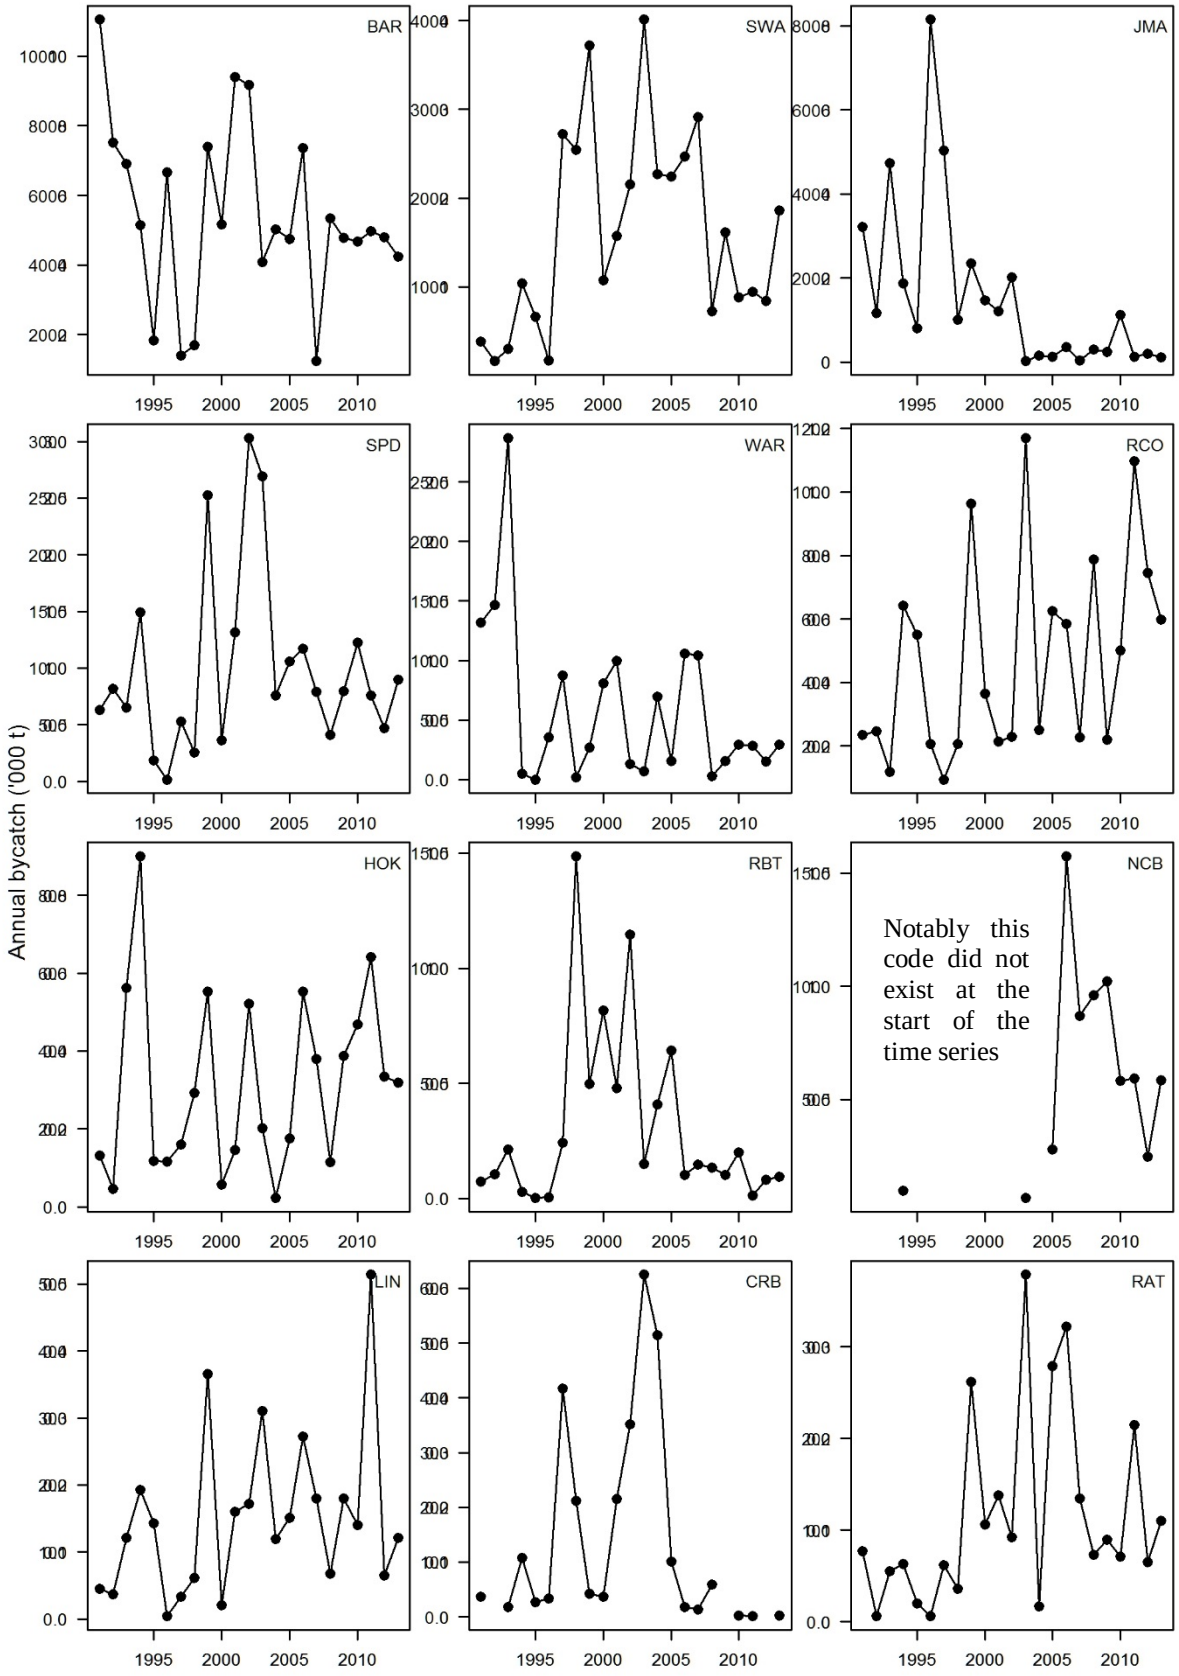

Figure 1b: Annual bycatch estimates for key arrow squid fishery bycatch species between 1990–91 and 2012–13. See http://marlin.niwa.co.nz for species code definitions. Note: the scale changes on the y-axis between plots. Trends implied by codes which did not exist at the start of the time series are indicated on the graphs.

Hoki, hake, ling trawl fishery

- Of the 340 bycatch species examined, 143 have shown a decrease in catch over time and 197 an increase in catch; with 40 having shown a significant decrease and 19 an increase in catch.
- The species showing the greatest decline were skates (SKA), combined jack mackerel species (JMA, JMM, and JMN), and dogfishes (*Etmopterus* spp., ETM) (Figure 2a).
- The species showing the greatest increase were Tam O shanter urchins (Echinothurioida, TAM), umbrella octopus (*Opisthoteuthis* spp., OPI), and floppy tubular sponge (*Hyalascus* sp., HYA), (Figure 2a).
- The most commonly caught bycatch species were silver warehou (SWA), javelinfish (JAV), unspecified rattails (Macrouridae, RAT) (Figure 2b). The other twelve next most common bycatch species are also shown in Figure 2b.
- Annual catch was often higher for the precision based estimates than for coarse estimates, but the overall trend was often similar (Figure2c).

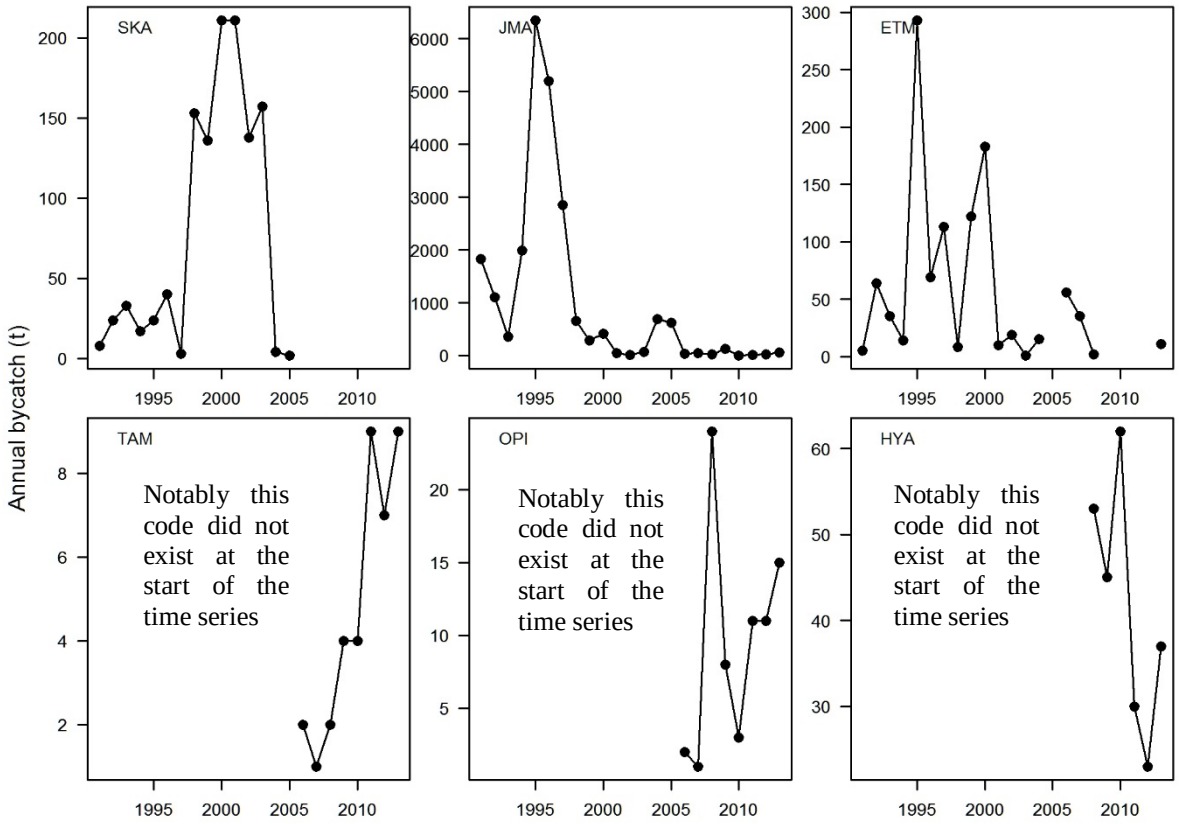

Figure 2a: Annual bycatch estimates in the hoki, hake, and ling trawl fishery for the species which have shown the greatest decrease (top) and greatest increase (bottom) between 1990–91 and 2012–13. See text above for explanation of the species codes. Note: skates (SKA) were mainly recorded as rough skate (RSK) or smooth skate (SSK) after 2002–03; some species (e.g., the sponge HYA and the octopus OPI) may not have been well identified in earlier years. Note: the scale changes on the y-axis between plots. Lines are joined where there are data points for consecutive years. Trends implied by codes which did not exist at the start of the time series are indicated on the graphs.

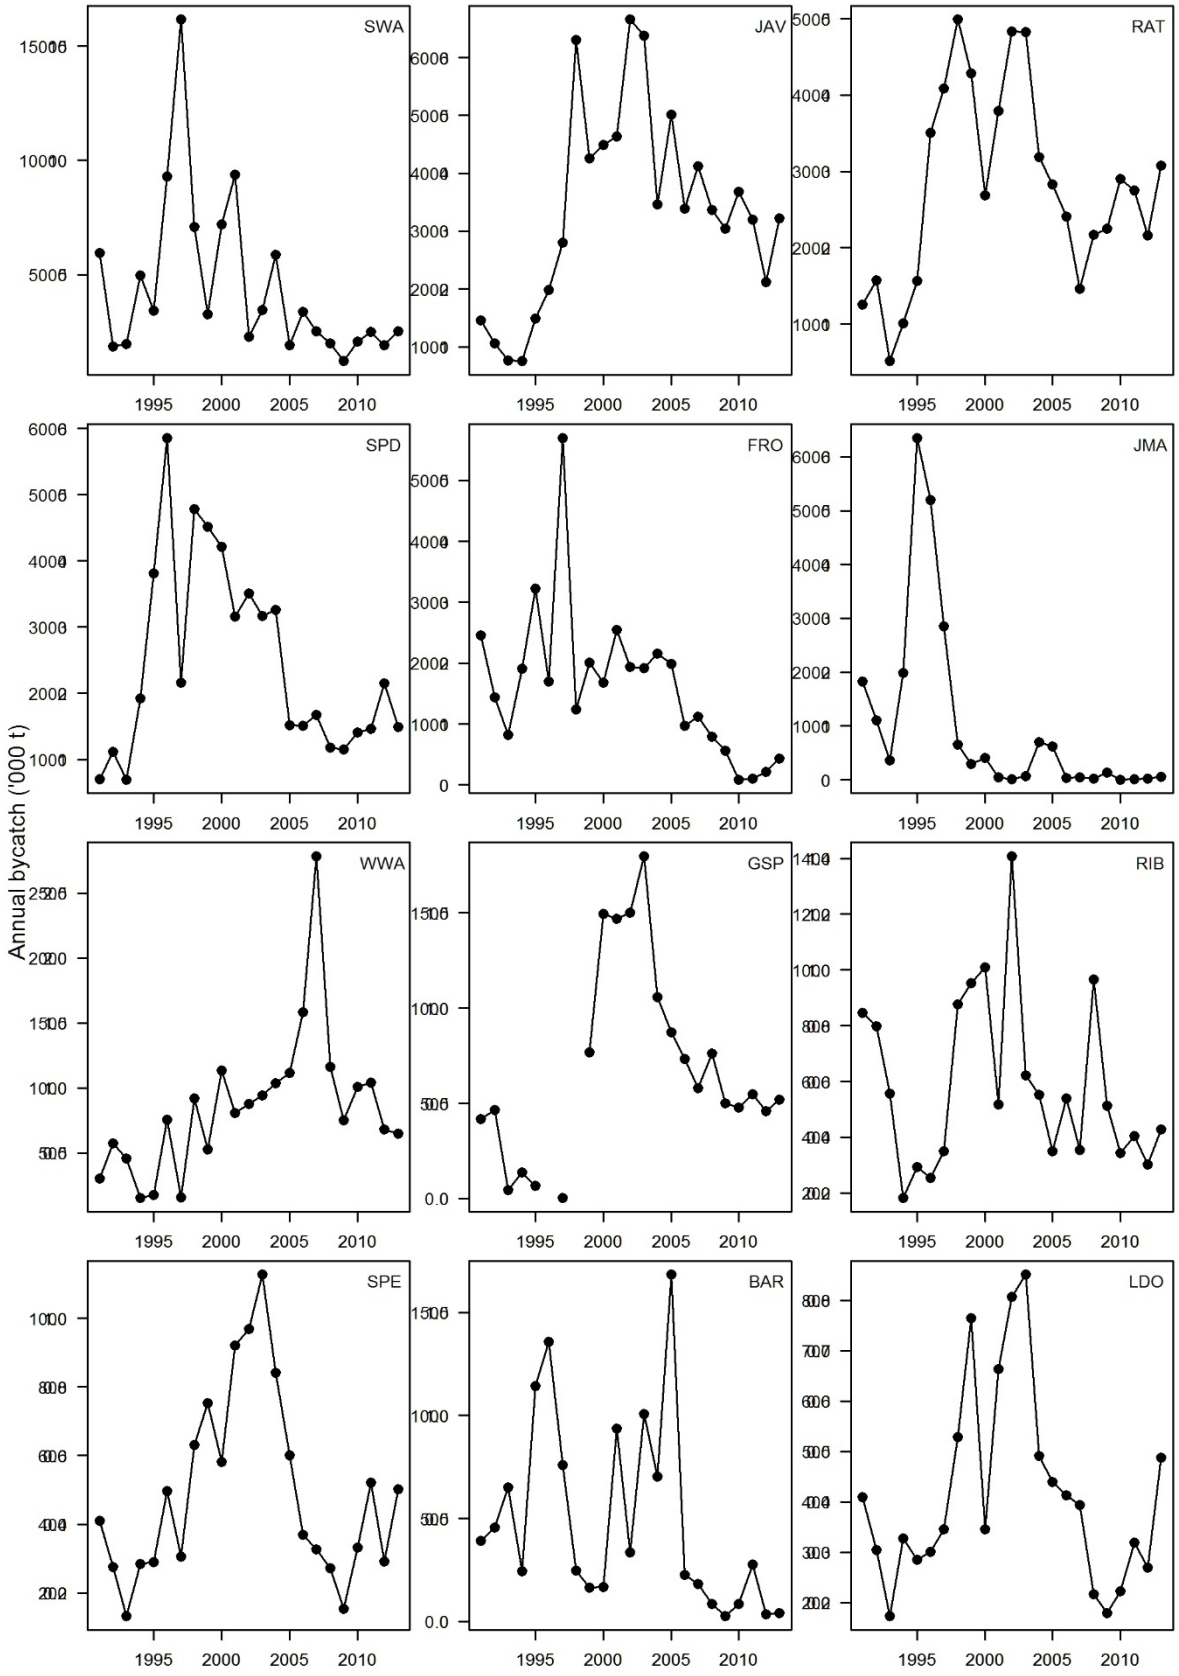

Figure 2b: Annual bycatch estimates for key hoki, hake, and ling fishery bycatch species between 1990–91 and 2012–13. See http://marlin.niwa.co.nz for species code definitions. Note: the scale changes on the y-axis between plots. Lines are joined where there are data points for consecutive years.

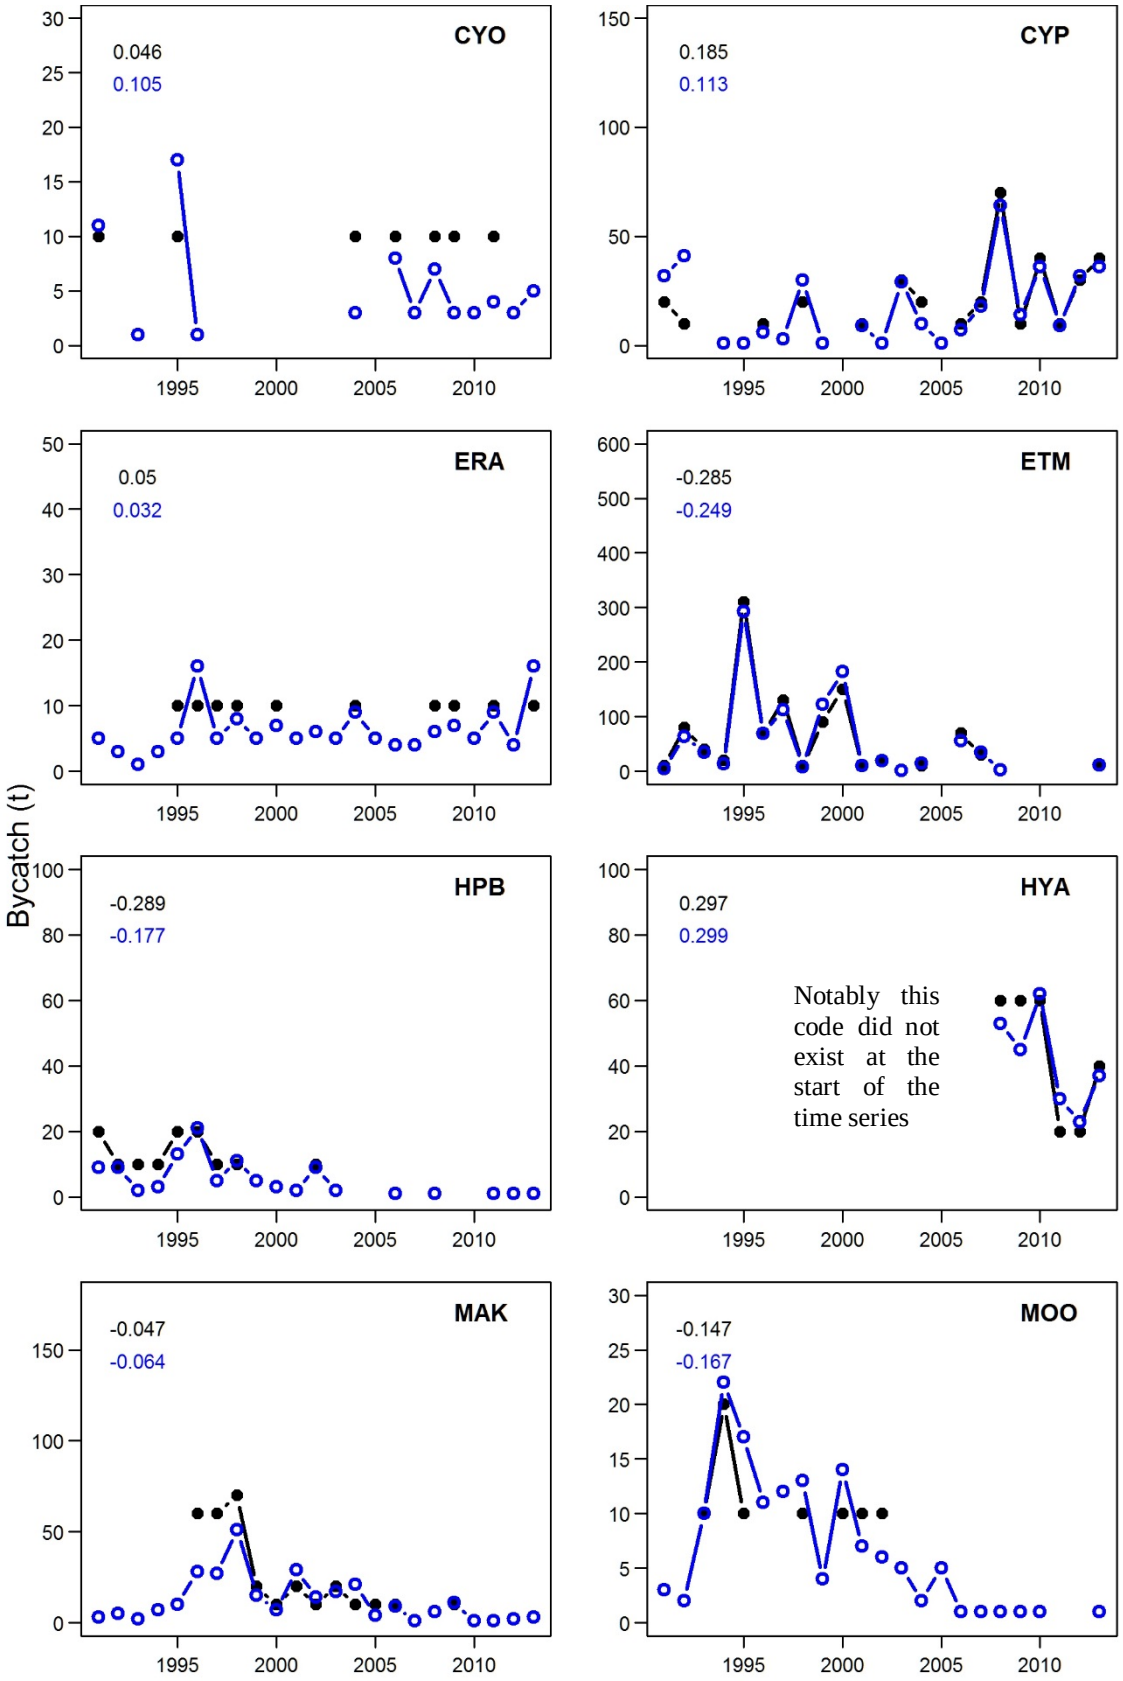

Figure 2c: Annual bycatch estimates for key hoki, hake, and ling fishery bycatch species between 1990–91 and 2012–13 for coarse (blue) and precision (black) based estimates of selected species. Numbers are the slope coefficient for a loglinear regression fitted to the data. See http://marlin.niwa.co.nz for species code definitions. Lines are joined where there are data points for consecutive years. Trends implied by codes which did not exist at the start of the time series are indicated on the graphs.

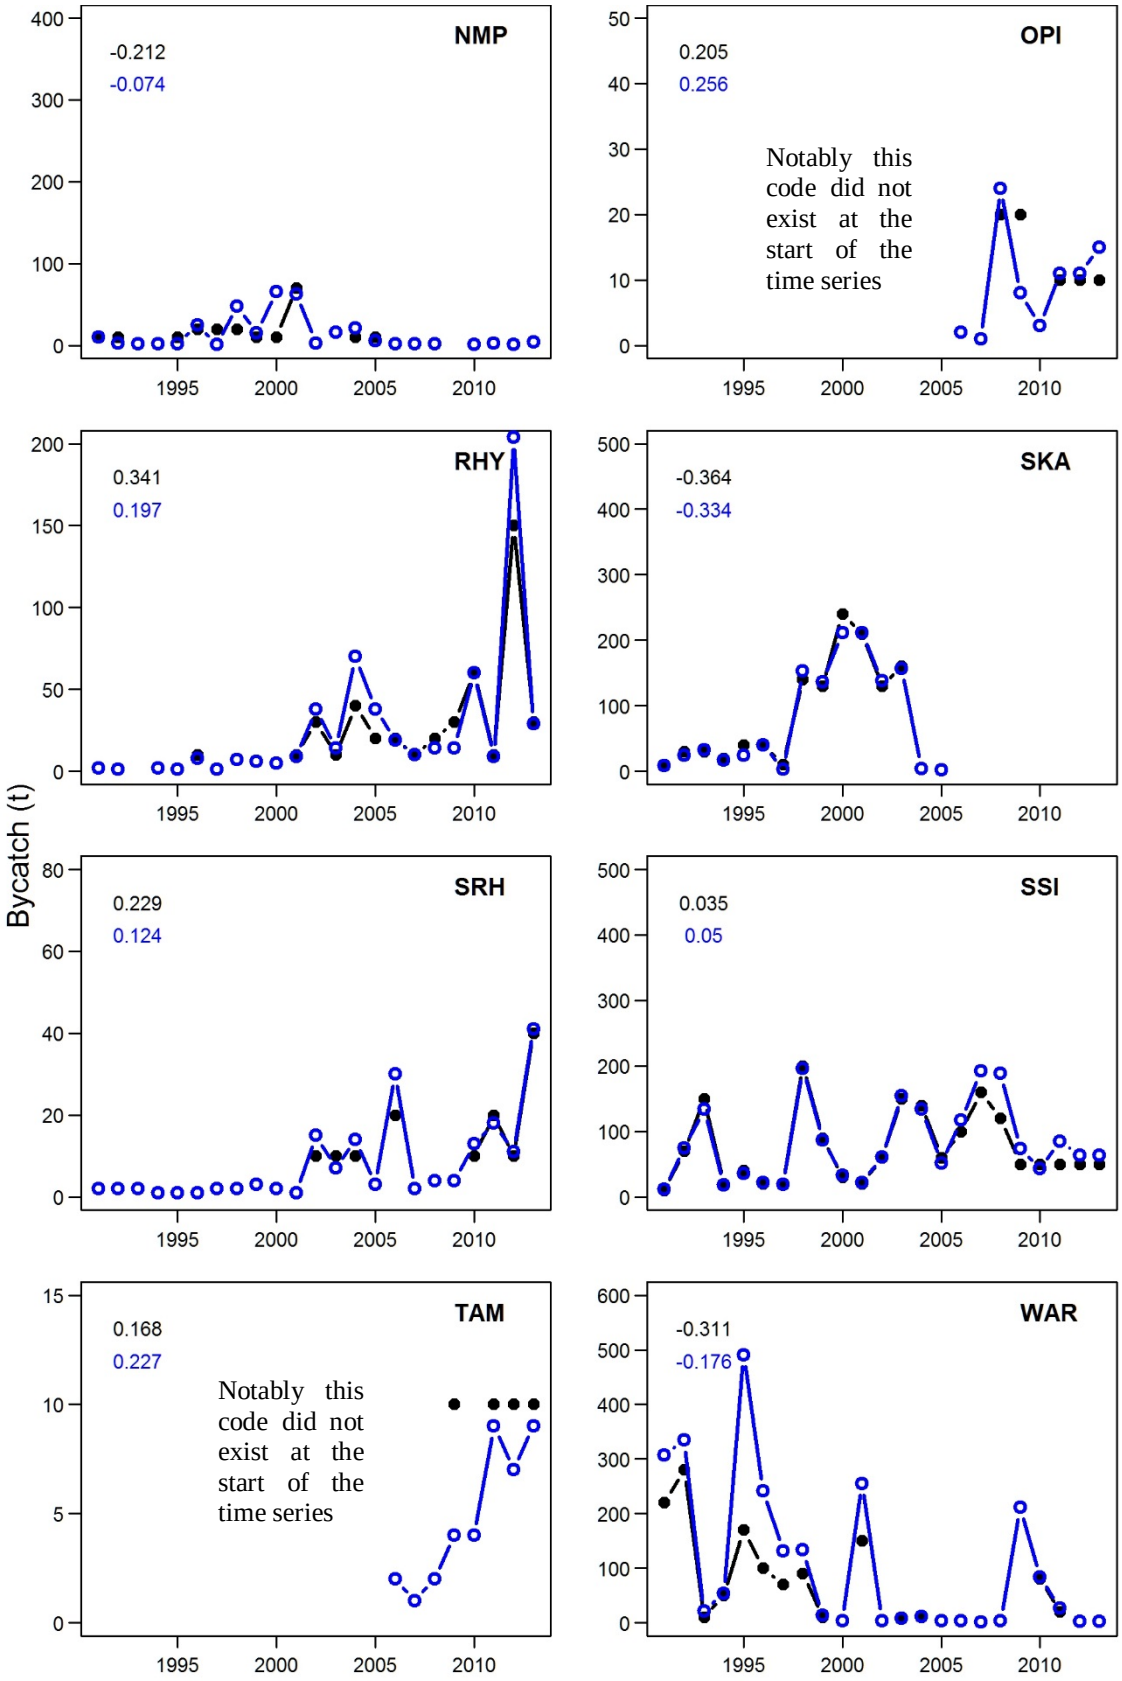

Figure 2c: continued.

Jack mackerel trawl fishery

- Of the 110 bycatch species examined, 65 have shown a decrease in catch over time and 45 an increase in catch; with 11 having shown a significant decrease and 10 a significant increase in catch.
- The species showing the greatest decline were dark ghost shark (GSH), sea perch (*Helicolenus* spp., SPE), and carpet shark (*Cephaloscyllium isabellum*, CAR) (Figure 3a).
- The species showing the greatest increase were silver dory (*Cyttus novaezealandiae*), kingfish (*Seriola lalandi*), and pilchard (*Sardinops sagax*) (Figure 3a).

The most commonly caught bycatch species were barracouta (BAR), blue mackerel (*Scomber australasicus*, EMA), and frostfish (*Lepidopus caudatus*, FRO). The other twelve next most common bycatch species are also shown in Figure 3b.

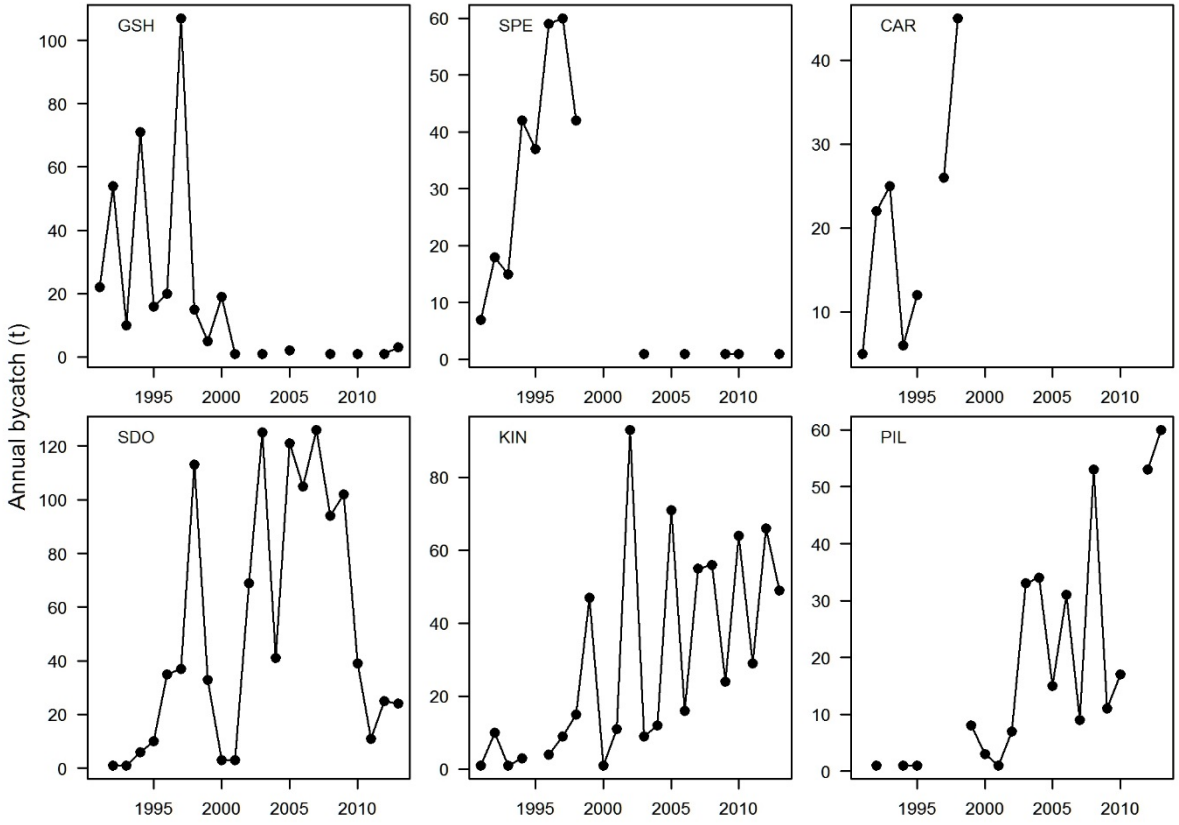

Figure 3a: Annual bycatch estimates in the jack mackerel trawl fishery for the species which have shown the greatest decrease (top) and greatest increase (bottom) between 1990–91 and 2012–13. See text above for explanation of the species codes. Note: the scale changes on the y-axis between plots. Lines are joined where there are data points for consecutive years.

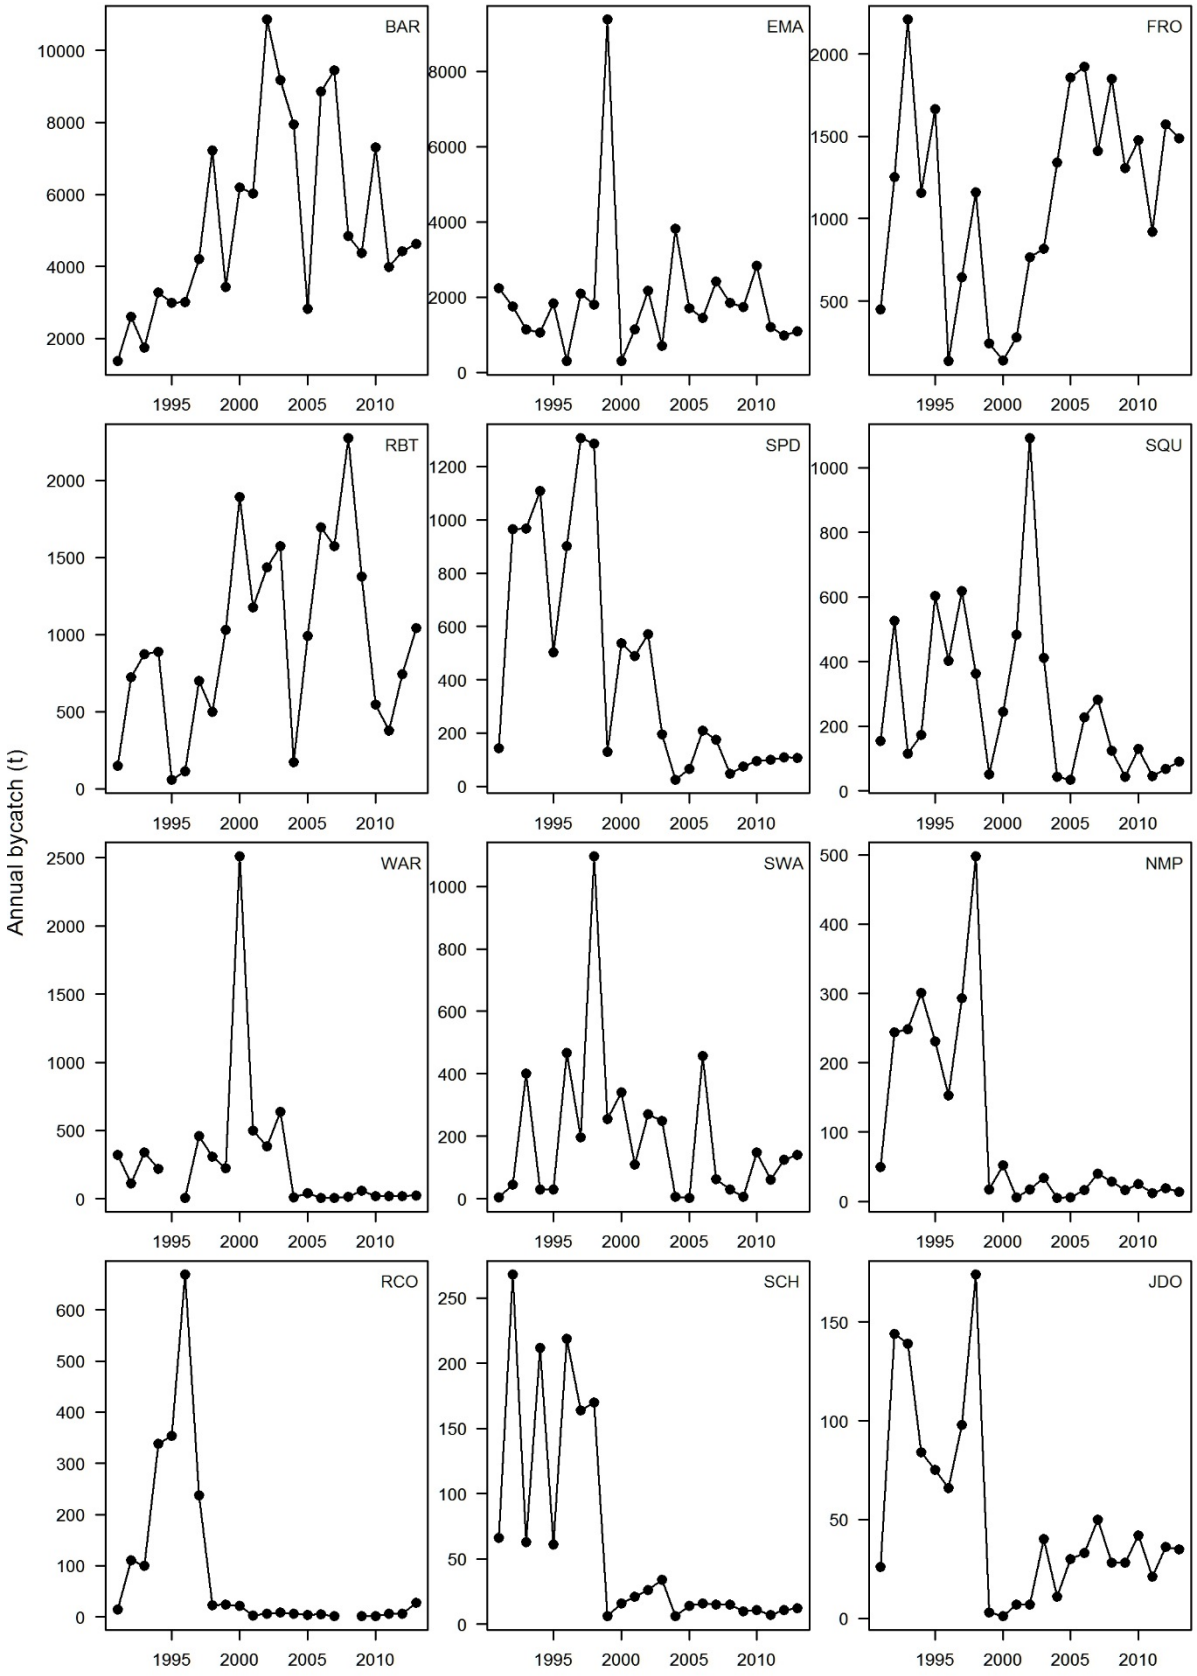

Figure 3b: Annual bycatch estimates for key jack mackerel fishery bycatch species between 1990–91 and 2012–13. See http://marlin.niwa.co.nz for species code definitions. Note: the scale changes on the y-axis between plots. Lines are joined where there are data points for consecutive years.

Ling longline fishery

- Observers began monitoring this fishery in 1992–93, therefore bycatch estimates are not available for 1990–91 and 1991–92.
- Of the 104 bycatch species examined, 31 have shown a decrease in catch over time and 73 an increase in catch; with 5 having shown a significant decrease and 9 a significant increase in catch.
- Among the species showing the greatest decline were bluenose (*Hyperoglyphe antarctica*, BNS), Ray's bream (*Brama brama*, RBM), and hapuku (*Polyprion oxygeneios*, HAP) (Figure 4a). The pattern of decline in BNS is driven by a single outlier and therefore should be treated more cautiously.
- The species showing the greatest increase were the hairy conger (HCO), hagfish (*Eptratretus cirrhatus*, HAG), and pale ghost shark (*Hydrolagus bemisi*, GSP) (Figure 4a).
- The most commonly caught bycatch species were spiny dogfish (SPD), ribaldo (*Mora moro*, RIB), and smooth skate (*Dipturus innominatus*, SSK). The other twelve next most common bycatch species are also shown in Figure 4b.

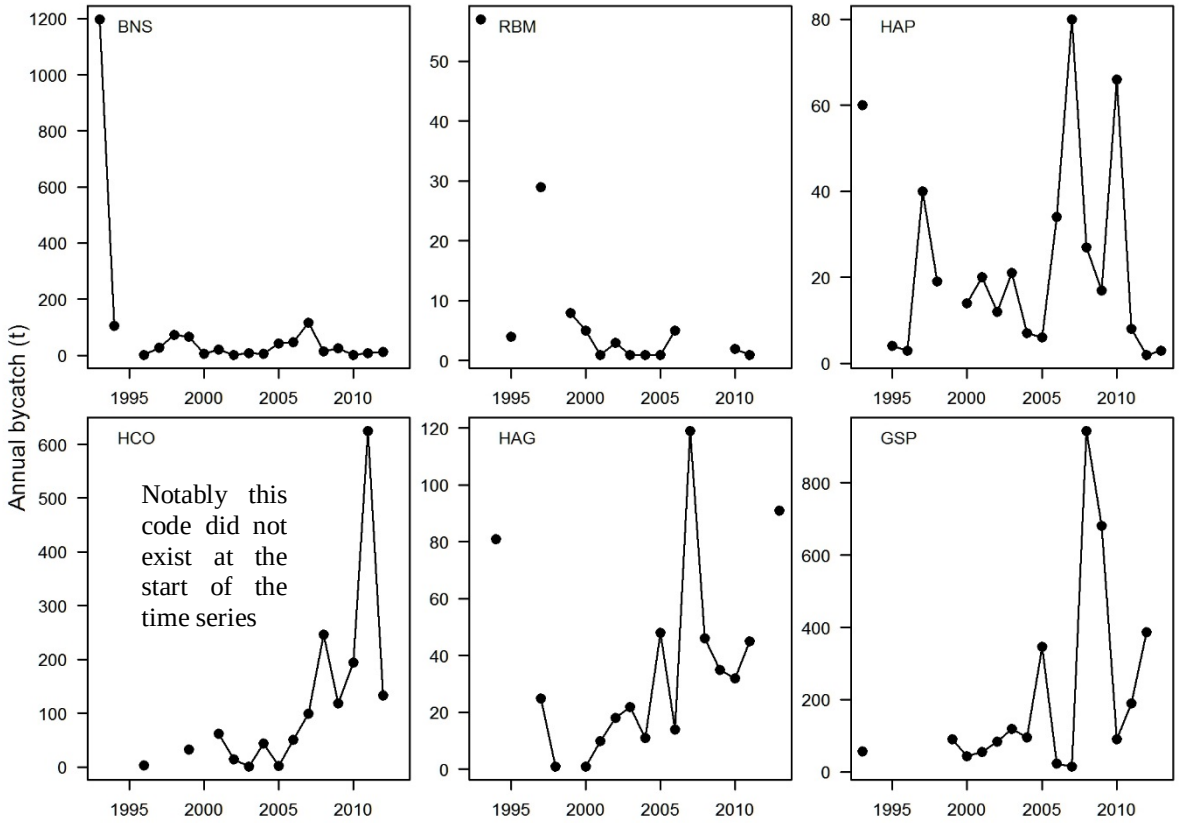

Figure 4a: Annual bycatch estimates in the ling longline fishery for the species which have shown the greatest decrease (top) and greatest increase (bottom) between 1990–91 and 2010–11. See text above for explanation of the species codes. Note: the scale changes on the y-axis between plots. Lines are joined where there are data points for consecutive years. Trends implied by codes which did not exist at the start of the time series are indicated on the graphs.

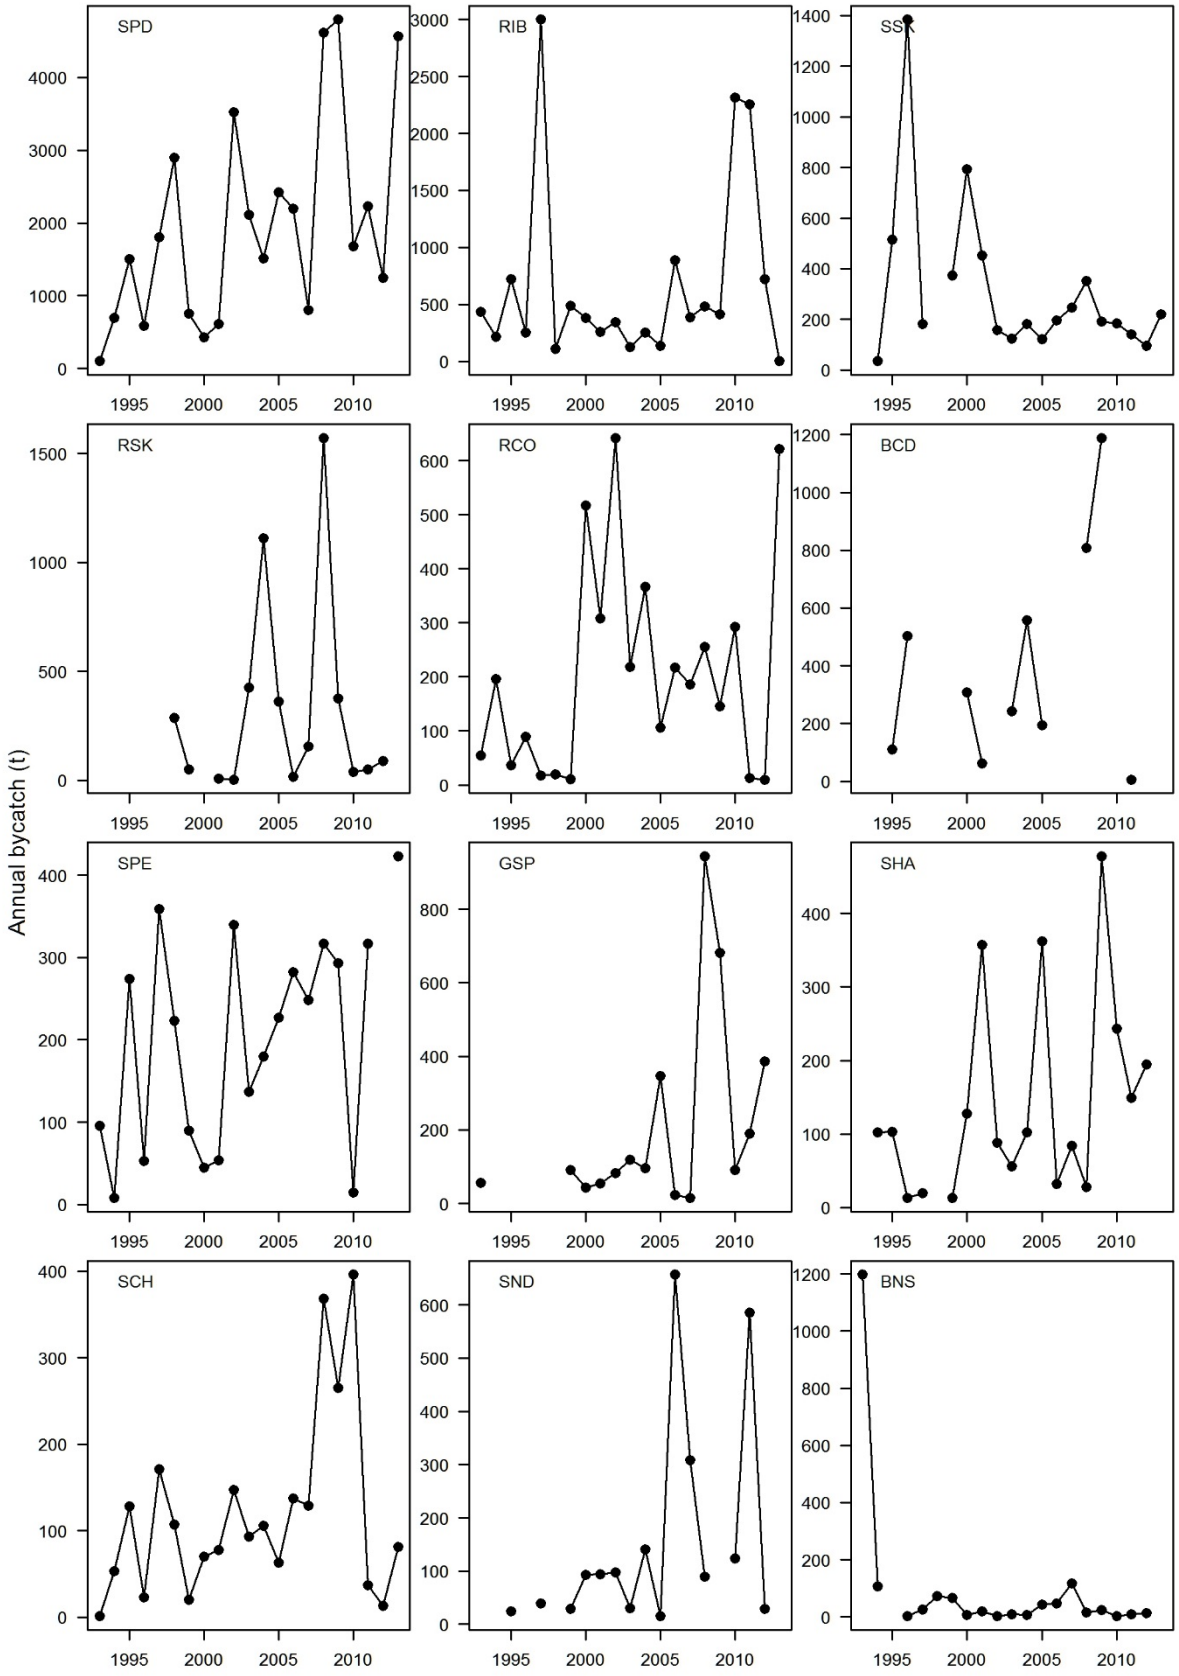

Figure 4b: Annual bycatch estimates for key ling longline fishery bycatch species between 1990–91 and 2012–13. See http://marlin.niwa.co.nz for species code definitions. Note: the scale changes on the y-axis between plots. Lines are joined where there are data points for consecutive years.

Orange roughy trawl fishery

- Of the 201 bycatch species examined, 101 have shown a decrease in catch over time and 100 an increase in catch; with 16 having shown a significant decrease and 26 a significant increase in catch.
- The species showing the greatest decline were spiny dogfish (SPD), black oreo (*Allocyttus niger*, BOE), and cardinalfishes (Epigonidae, CDL) (Figure 5a). The pattern of decline in SPD is driven by a single outlier and therefore should be treated more cautiously.
- The species showing the greatest increase were morid cods (Moridae, MOD), longnose velvet dogfish (*Centroscymnus crepidater*, CYP), and bushy hard coral (*Goniocorella dumosa*, GDU) (Figure 5a).
- The most commonly caught bycatch species were smooth oreo (*Pseudocyttus maculatus*, SSO), black oreo (*Allocyttus niger*, BOE), and black cardinalfish (*Epigonus telescopus*, CDL). The other twelve next most common bycatch species are also shown in Figure 5b.

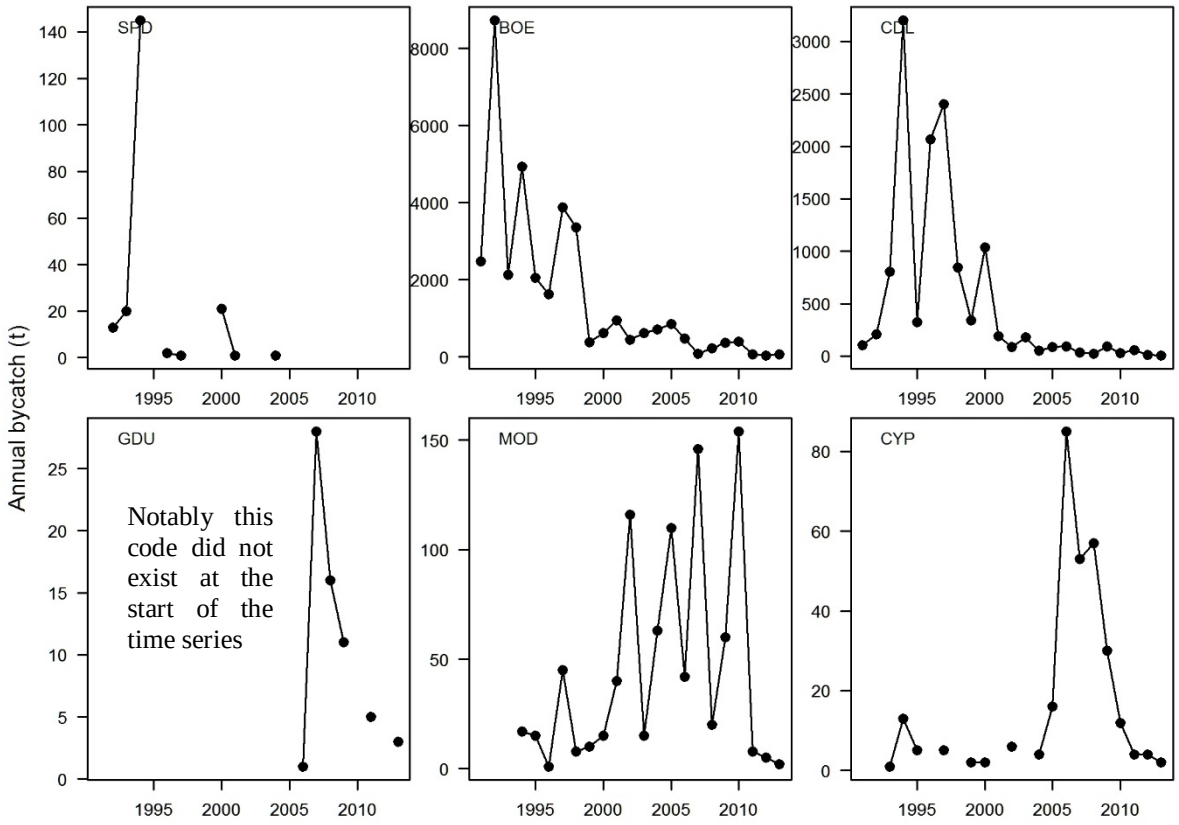

Figure 5a: Annual bycatch estimates in the orange roughy trawl fishery for the species which have shown the greatest decrease (top) and greatest increase (bottom) between 1990–91 and 2012–13. See text above for explanation of the species codes. Note: *Goniocorella dumosa* may not have been well identified before 2005–06. Note: the scale changes on the y-axis between plots. Lines are joined where there are data points for consecutive years. Trends implied by codes which did not exist at the start of the time series are indicated on the graphs.

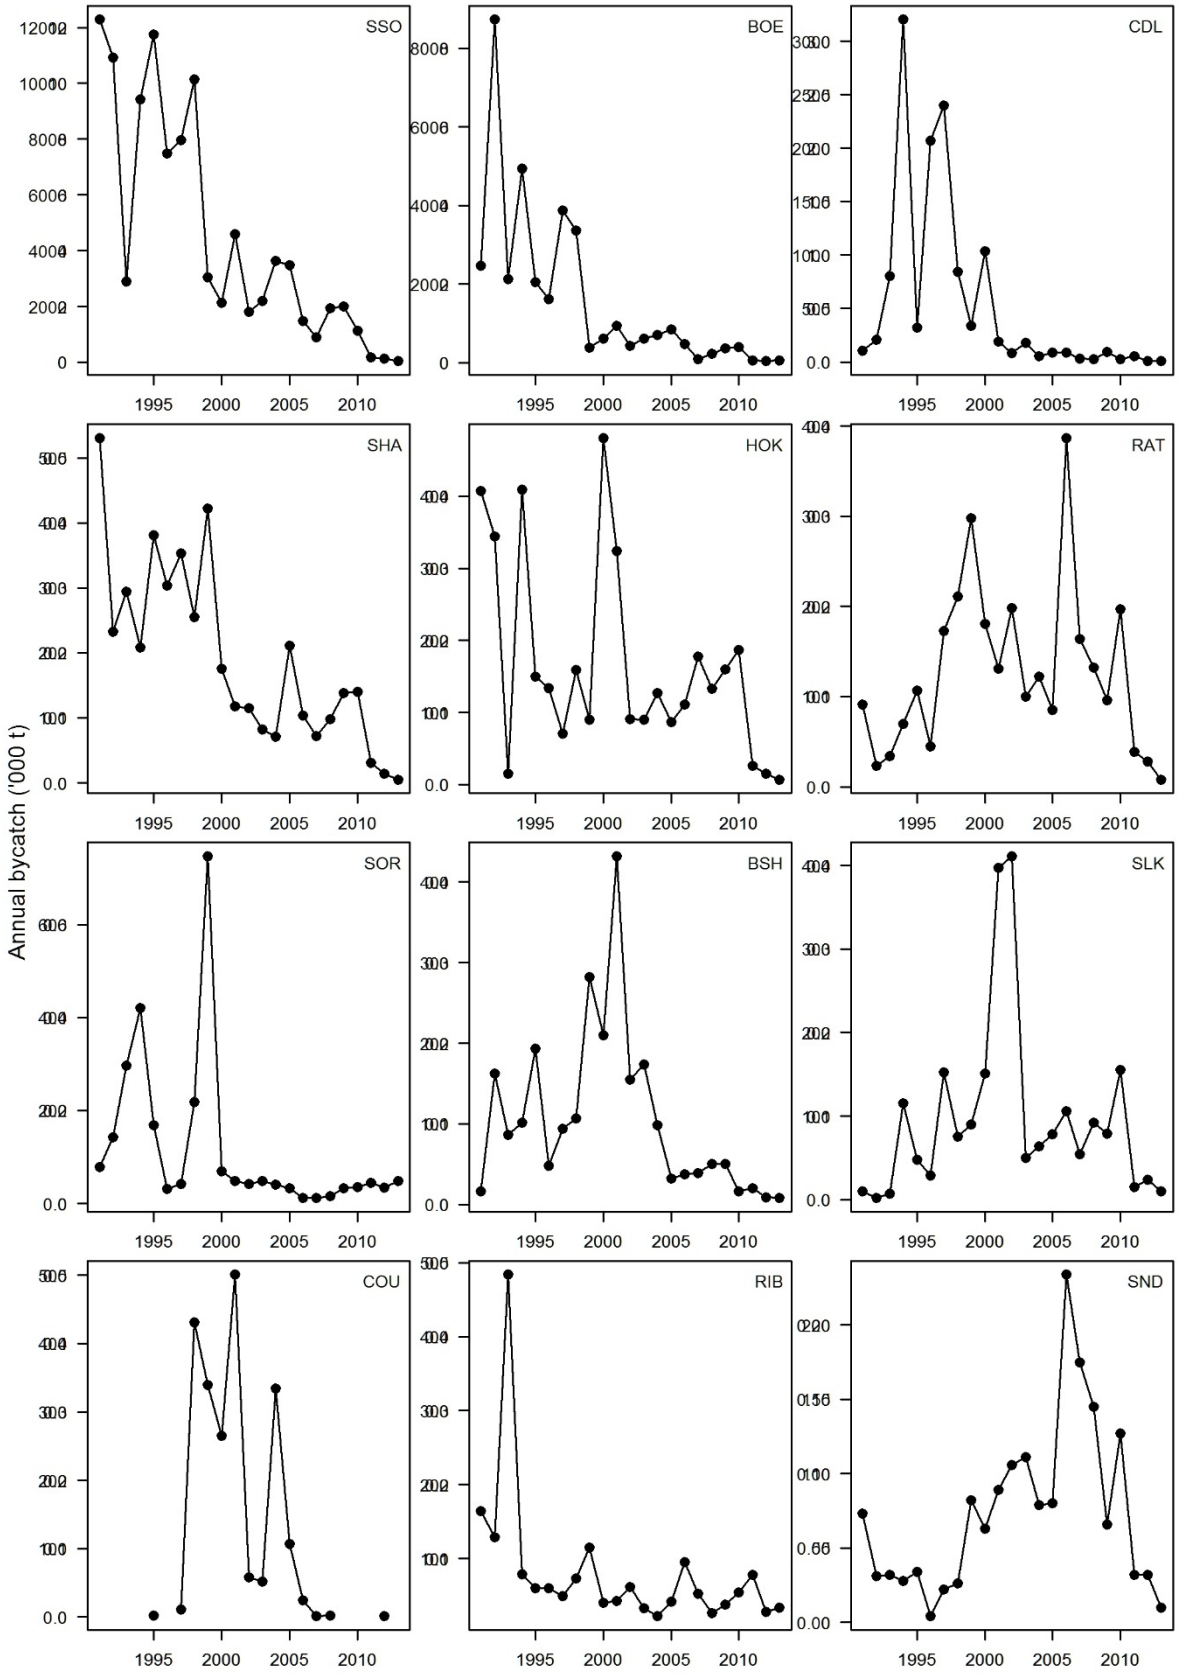

Figure 5b: Annual bycatch estimates for key orange roughy trawl fishery bycatch species between 1990–91 and 2012–13. See http://marlin.niwa.co.nz for species code definitions. Note: the scale changes on the y-axis between plots. Lines are joined where there are data points for consecutive years.

Oreo trawl fishery

- Of the 116 bycatch species examined, 46 have shown a decrease in catch over time and 70 an increase in catch; with 19 having shown a significant decrease and 8 a significant increase in catch.
- The species showing the greatest decline were dark ghost shark (GSH), unspecified shark (SHA), and ling (LIN) (Figure 6a). The pattern of decline in GSH is driven by a single outlier and therefore should be treated more cautiously.
- The species showing the greatest increase were ridge-scaled rattail (*Macrourus carinatus*, MCA), Baxter's lantern dogfish (*Etmopterus baxteri*, ETB), and pale ghost shark (GSP) (Figure 6a).
- The most commonly caught bycatch species were orange roughy (*Hoplostethus atlanticus*, ORH), unspecified shark (SHA), and hoki (HOK). The other twelve next most common bycatch species are also shown in Figure 6b.

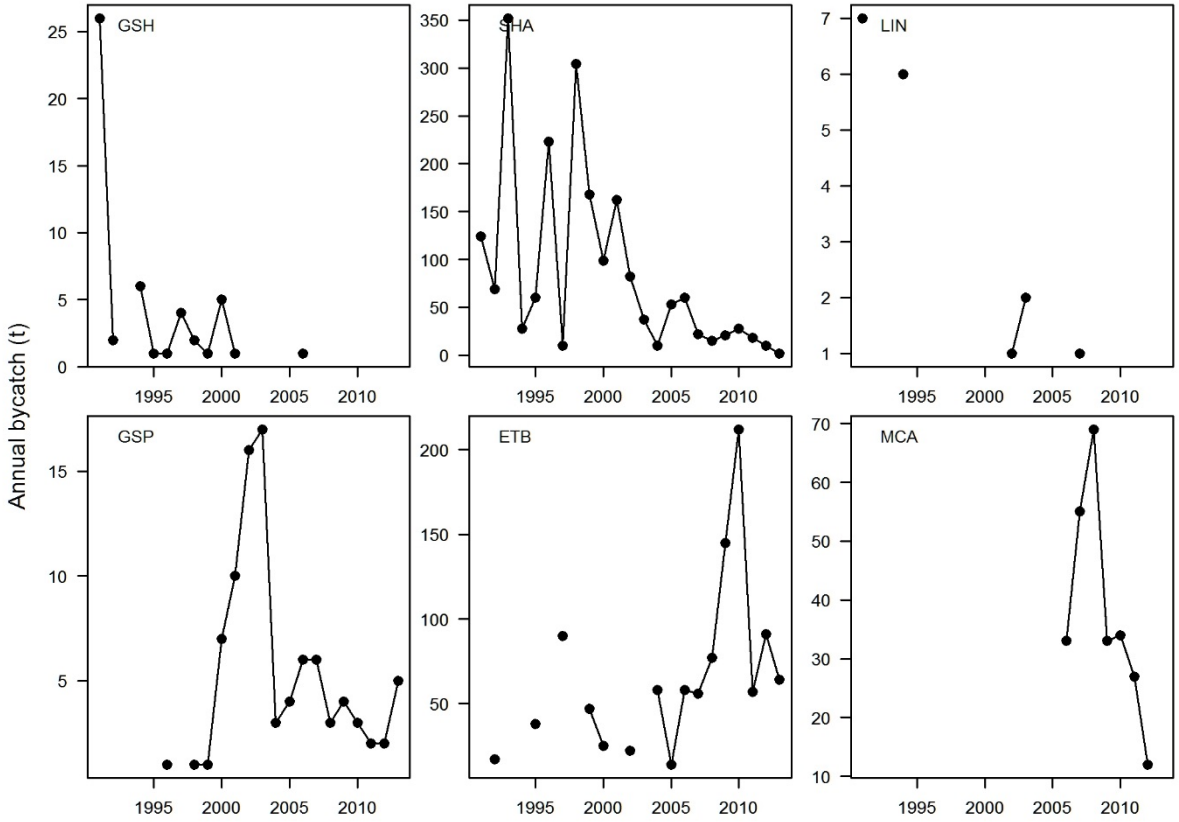

Figure 6a: Annual bycatch estimates in the oreo trawl fishery for the species which have shown the greatest decrease (top) and greatest increase (bottom) between 1990–91 and 2012–13. See text above for explanation of the species codes. Note: sharks (SHA) may have been identified to an increasingly higher taxonomic level over time; rattails such as MCA may not have been well identified in earlier years. Note: the scale changes on the y-axis between plots. Lines are joined where there are data points for consecutive years.

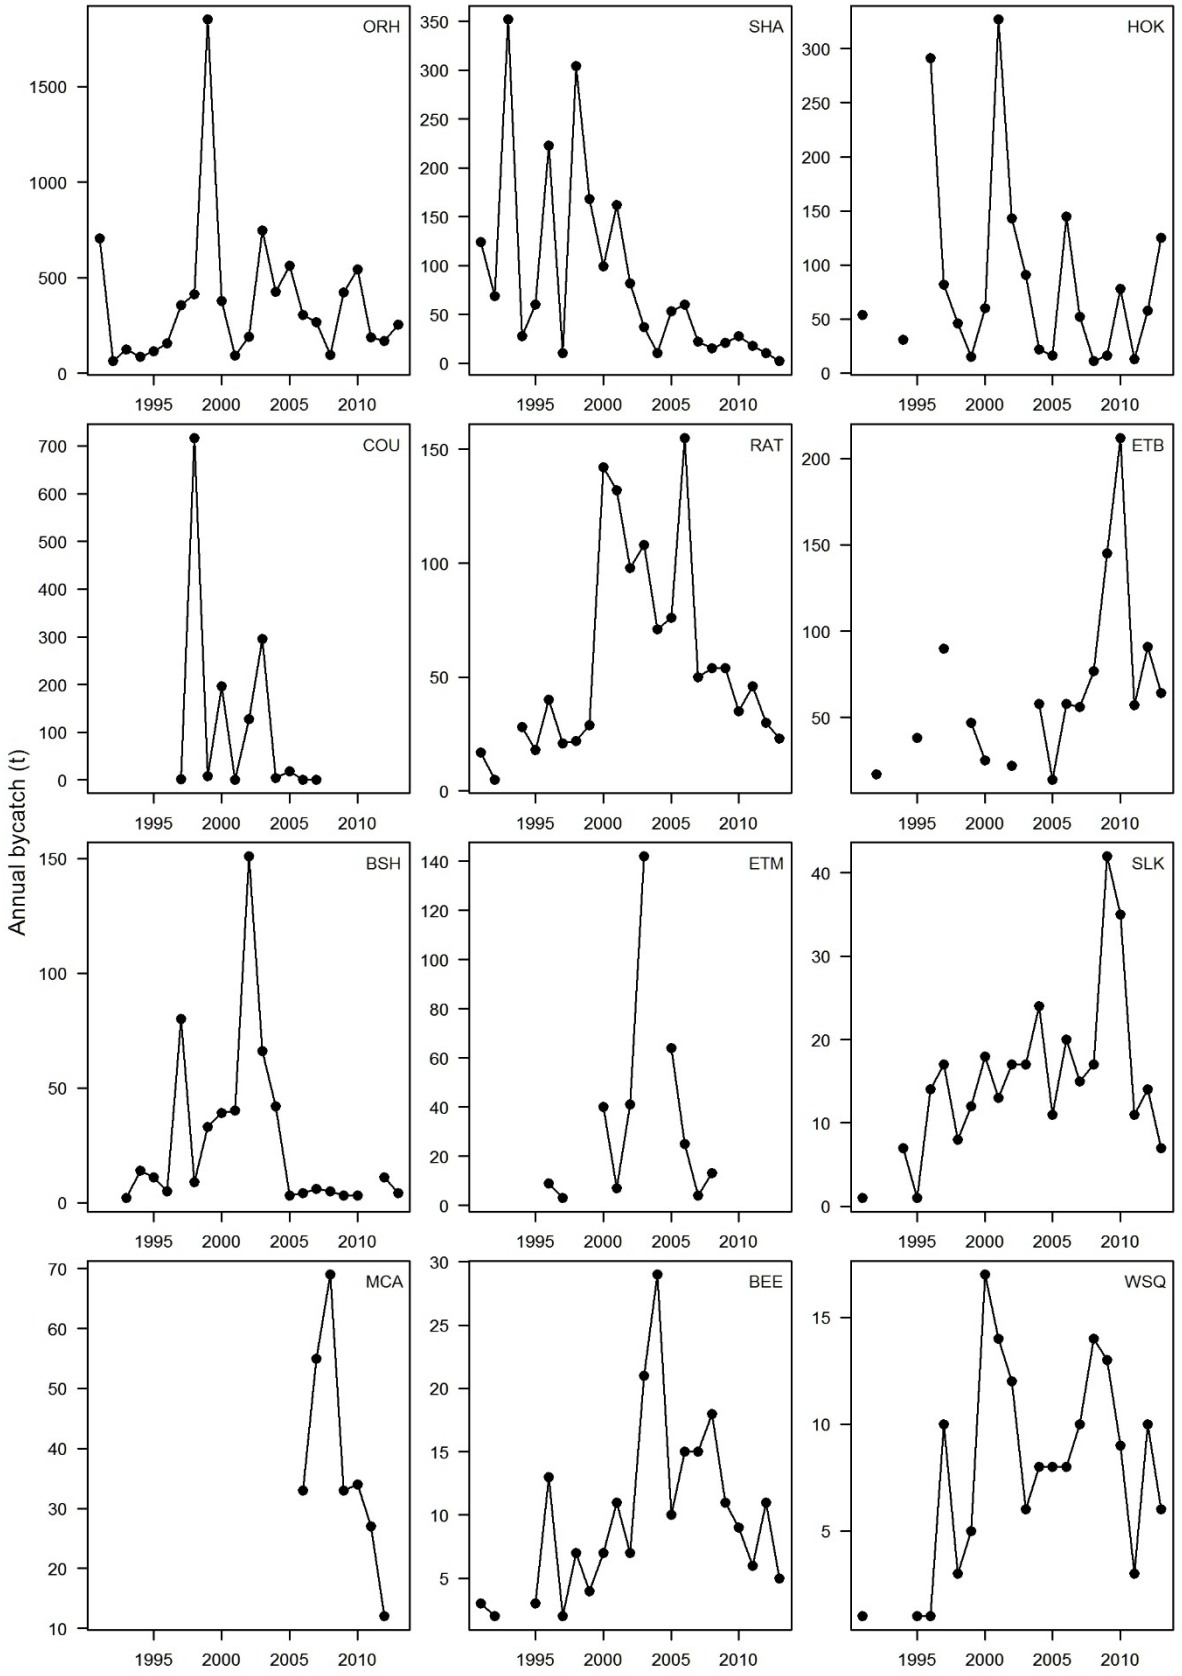

Figure 6b: Annual bycatch estimates for key oreo fishery bycatch species between 1990–91 and 2012–13. See http://marlin.niwa.co.nz for species code definitions. Note: the scale changes on the y-axis between plots. Lines are joined where there are data points for consecutive years.

Scampi trawl fishery

- Of the 267 bycatch species examined, 115 have shown a decrease in catch over time and 152 an increase in catch; with 16 having shown a significant decrease and 12 a significant increase in catch.
- The species showing the greatest decline were skates (Rajidae and Arhynchobatidae, SKA), bluenose (*Hyperoglyphe antarctica*, BNS) and alfonsino (*Beryx* spp., BYX) (Figure 7a).
- The species showing the greatest increase were Geometric star (*Psilaster acuminatus*, PSI), frilled crab (*Trichopeltarion fantasticum*, TFA), and spiny masking crab (*Teratomaia richardsoni*, SMK) (Figure 7a).
- The most commonly caught bycatch species were javelinfish (*Lepidorhynchus denticulatus*, JAV), unspecified rattails (Macrouridae, RAT), and sea perch (*Helicolenus* spp., SPE). The other twelve next most common bycatch species are also shown in Figure 7b.

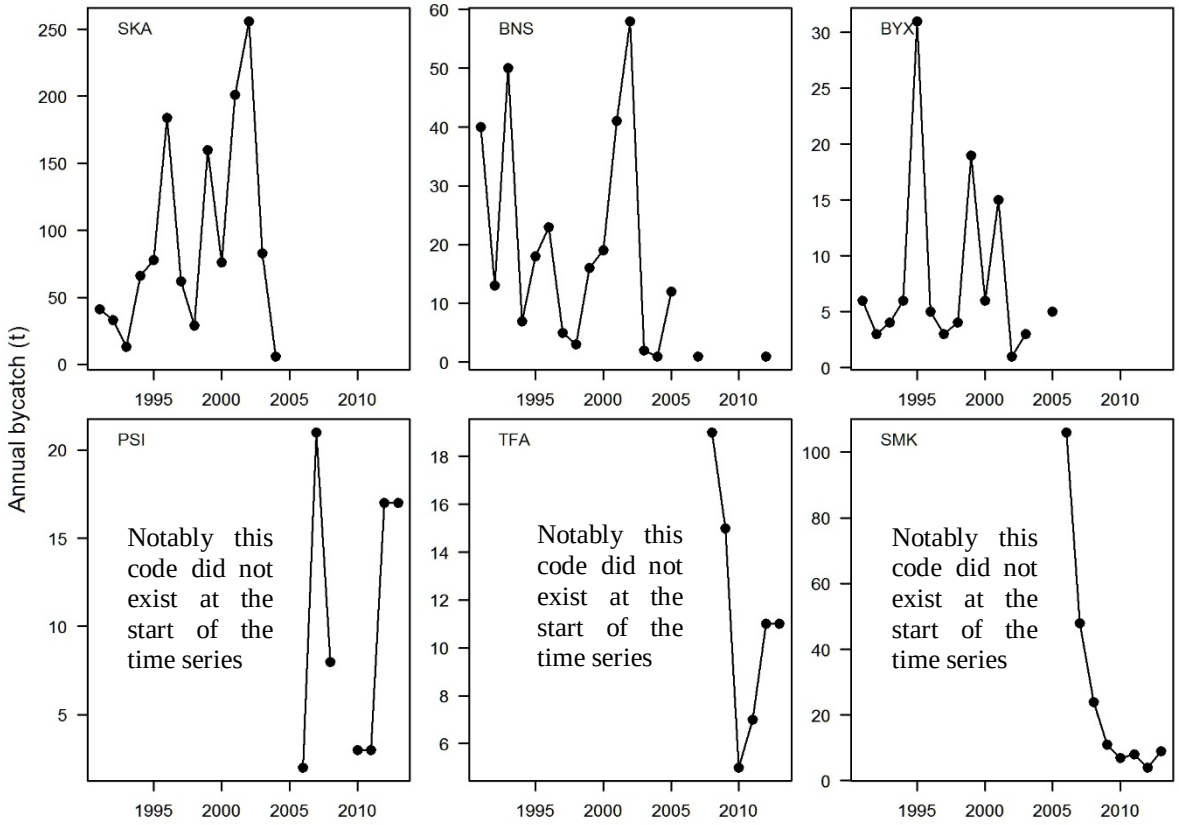

Figure 7a: Annual bycatch estimates in the scampi trawl fishery for the species which have shown the greatest decrease (top) and greatest increase (bottom) between 1990–91 and 2012–13. See text above for explanation of the species codes. Note: skates (SKA) were mainly recorded as rough skate (RSK) or smooth skate (SSK) after 2002–03; spiny masking crabs may not have been well identified before 2004–05. Note: the scale changes on the y-axis between plots. Lines are joined where there are data points for consecutive years. Trends implied by codes which did not exist at the start of the time series are indicated on the graphs.

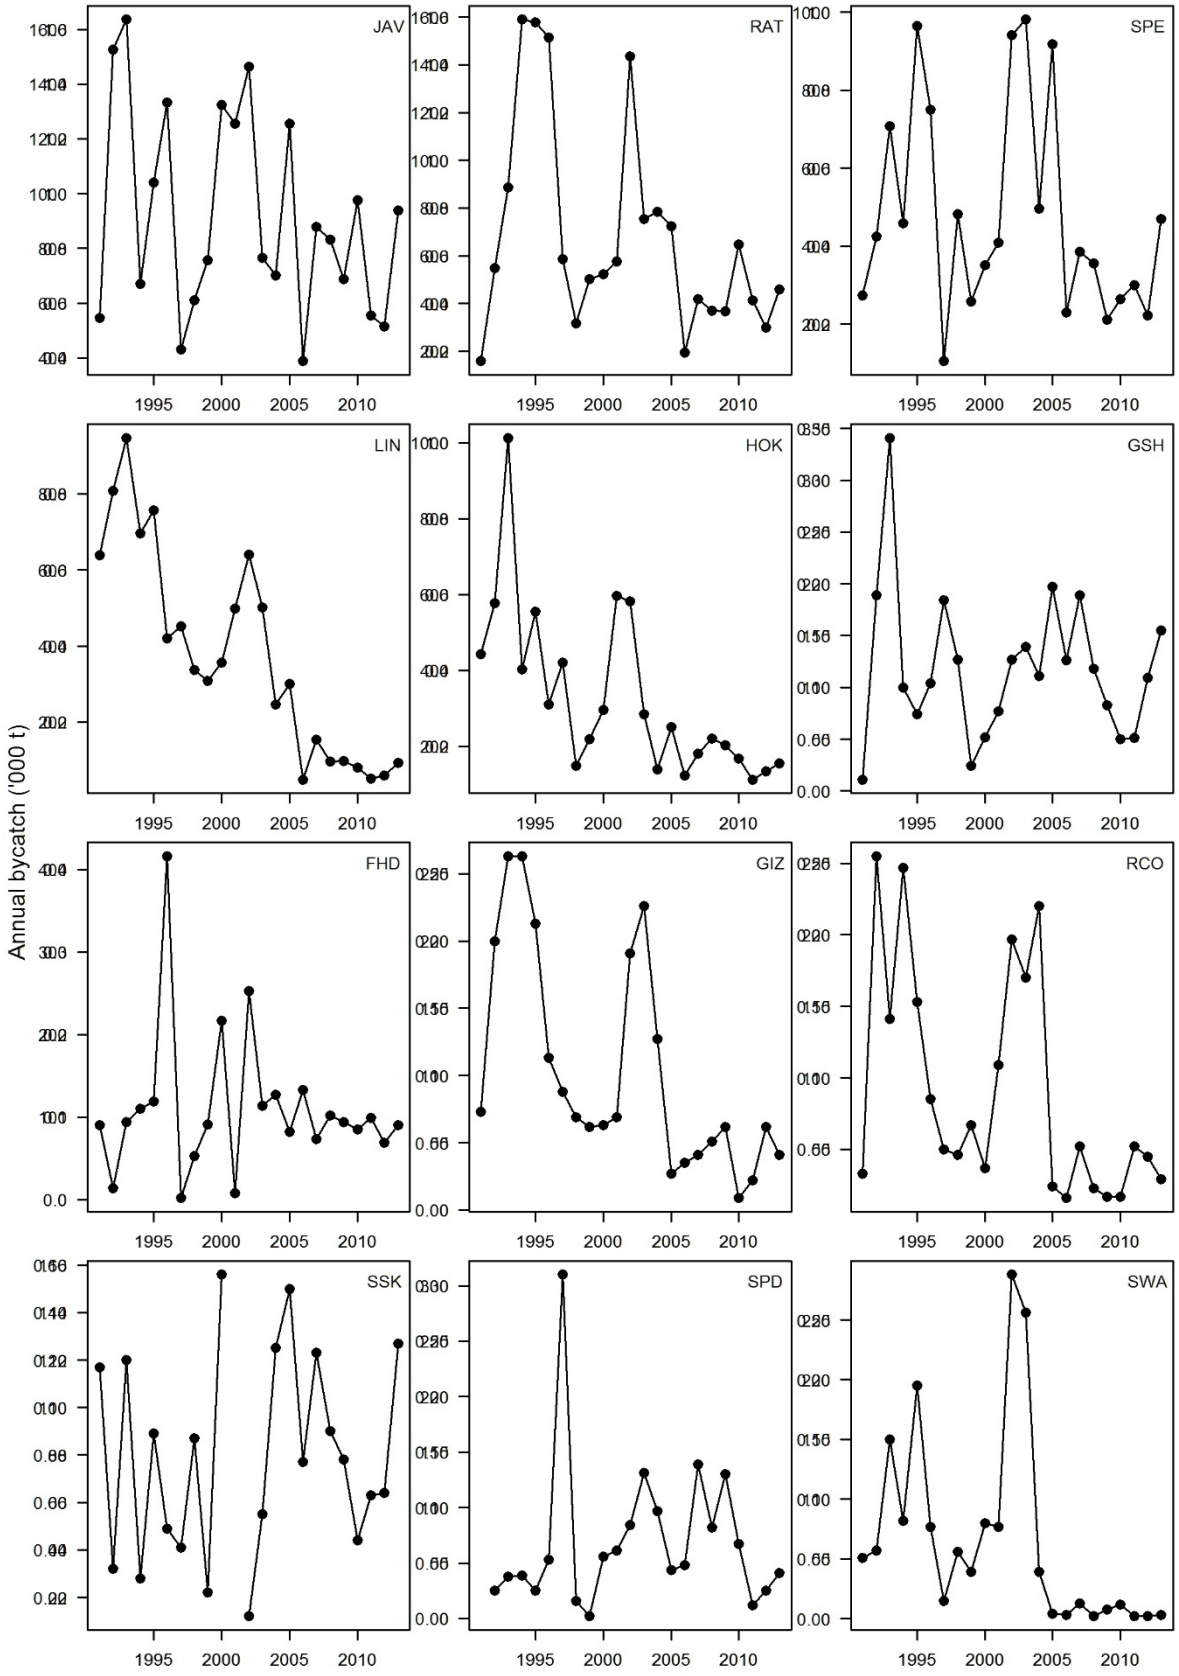

Figure 7b: Annual bycatch estimates for key scampi fishery bycatch species between 1990–91 and 2012–13. See http://marlin.niwa.co.nz for species code definitions. Note: the scale changes on the y-axis between plots. Lines are joined where there are data points for consecutive years.

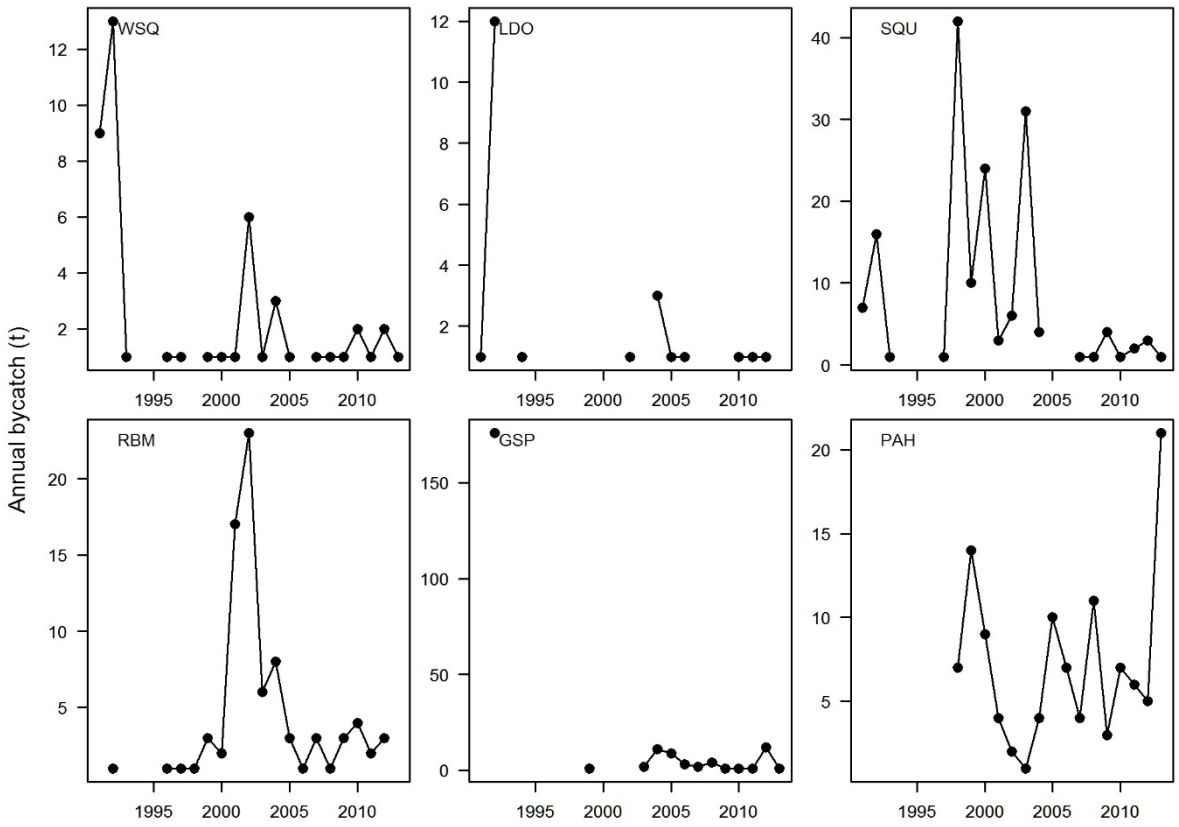
Southern blue whiting trawl fishery

- Of the 65 bycatch species examined, 36 have shown a decrease in catch over time and 29 an increase in catch; with 4 having shown a significant decrease and 11 a significant increase in catch.
- The species showing the greatest decline were warty squid (*Onykia* spp., WSQ), lookdown dory (*Cyttus traversi*, LDO) and arrow squid (*Nototodarus sloanii and N. gouldi*, SQU) (Figure 8a). The pattern of decline in LDO is driven by a single outlier and therefore should be treated more cautiously.
- The species showing the greatest increase were ray's bream (*Brama brama*, RBM), pale ghost shark (*Hydrolagus bemisi*, GSP), and opah (*Lampris immaculatus*, PAH) (Figure 8a). The patterns of increase in PAH is driven by a single outlier and therefore should be treated more cautiously.

The most commonly caught bycatch species were ling (*Genypterus blacodes*, LIN), hoki (*Macruronus novaezelandiae*, HOK), and hake (*Merluccius australis*, HAK). The other twelve next most common bycatch species are also shown in Figure 8b. The pattern of decline in GSP, LIN, HOK, SSI and SPD is driven by a single outlier and therefore should be treated more cautiously.



REDO Figure 8a: Annual bycatch estimates in the southern blue whiting trawl fishery for the species which have shown the greatest decrease (top) and greatest increase (bottom) between 1990–91 and 2012–13. See text above for explanation of the species codes. Note: the scale changes on the y-axis between plots. Lines are joined where there are data points for consecutive years.

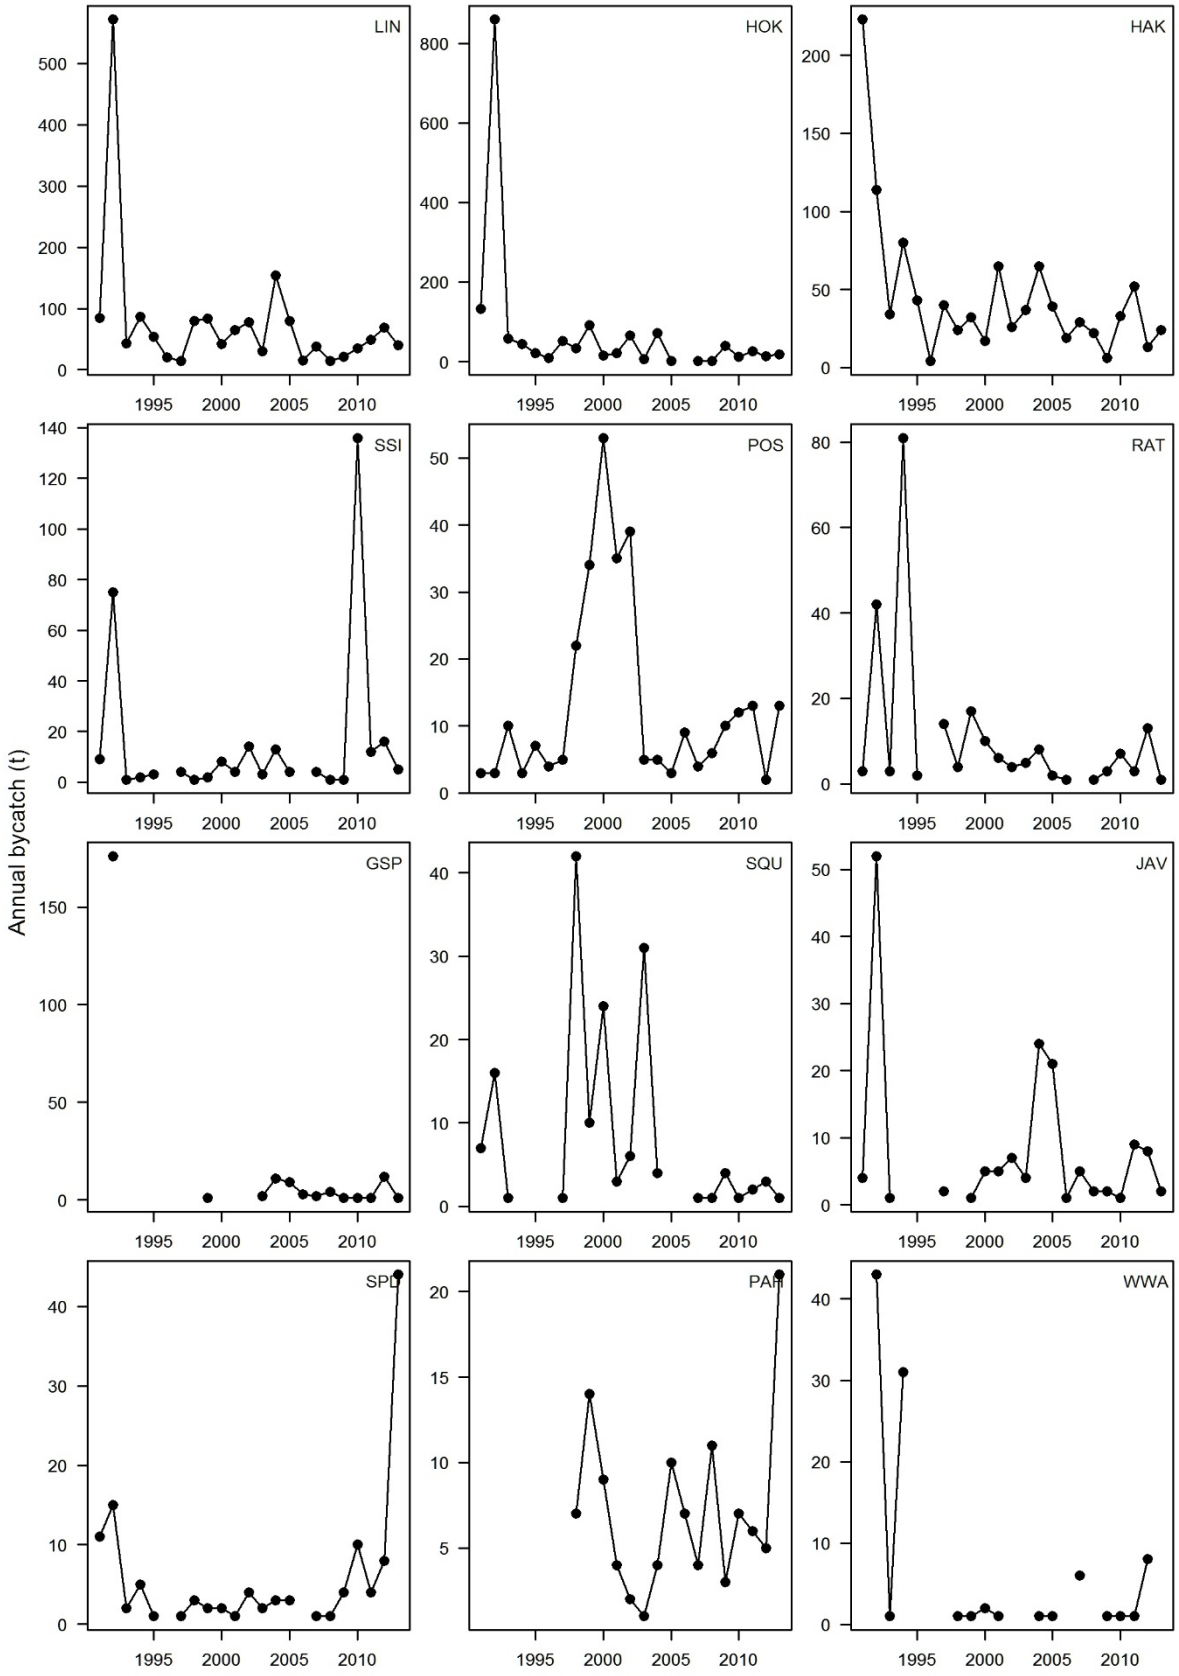


Figure 8b: Annual bycatch estimates for key southern blue whiting fishery bycatch species between 1990–91 and 2012–13. See http://marlin.niwa.co.nz for species code definitions. Note: the scale changes on the y-axis between plots. Lines are joined where there are data points for consecutive years.

In order to examine temporal trends for individual species or species groups across all eight fisheries, a summary of the slope coefficients for each species and fishery is provided in graphical form in Table 9. This shows a consistent increase (in six or more of the eight fisheries) for deepsea skates (*Notoraja* spp.), Baxters lantern dogfish (*Etmopterus baxteri*), pale ghost shark (*Hydrolagus bemisi*), and javelinfish (*Lepidorhynchus denticulatus*); and consistent declines for bluenose (*Hyperoglyphe antarctica*), ghost shark (*Hydrolagus novaezealandiae*), and skates (Rajidae and Arhynchobatidae). Care in interpretation of slope needs to be taken into account, especially for data poor species (see Figure 2c).

Overall fishery bycatch shows different levels of bycatch in different fisheries (Figure 9a). The hoki, hake or ling trawl target had higher bycatch levels from 1997–98 to 2003–04, and these then dropped substantially to 2011–12. Overall bycatch levels were the lowest in the orange roughy, oreo, and southern blue whiting trawl fisheries, and the ling longline fishery. Coarse and precision based estimates were similar for all fisheries (Figure 9b). There was a good match for the scampi, orange roughy, southern blue whiting and oreo fishery estimates, but low correlation for estimates for the ling longline fishery (Figure 9b). No obvious reasons for these differences were apparent.

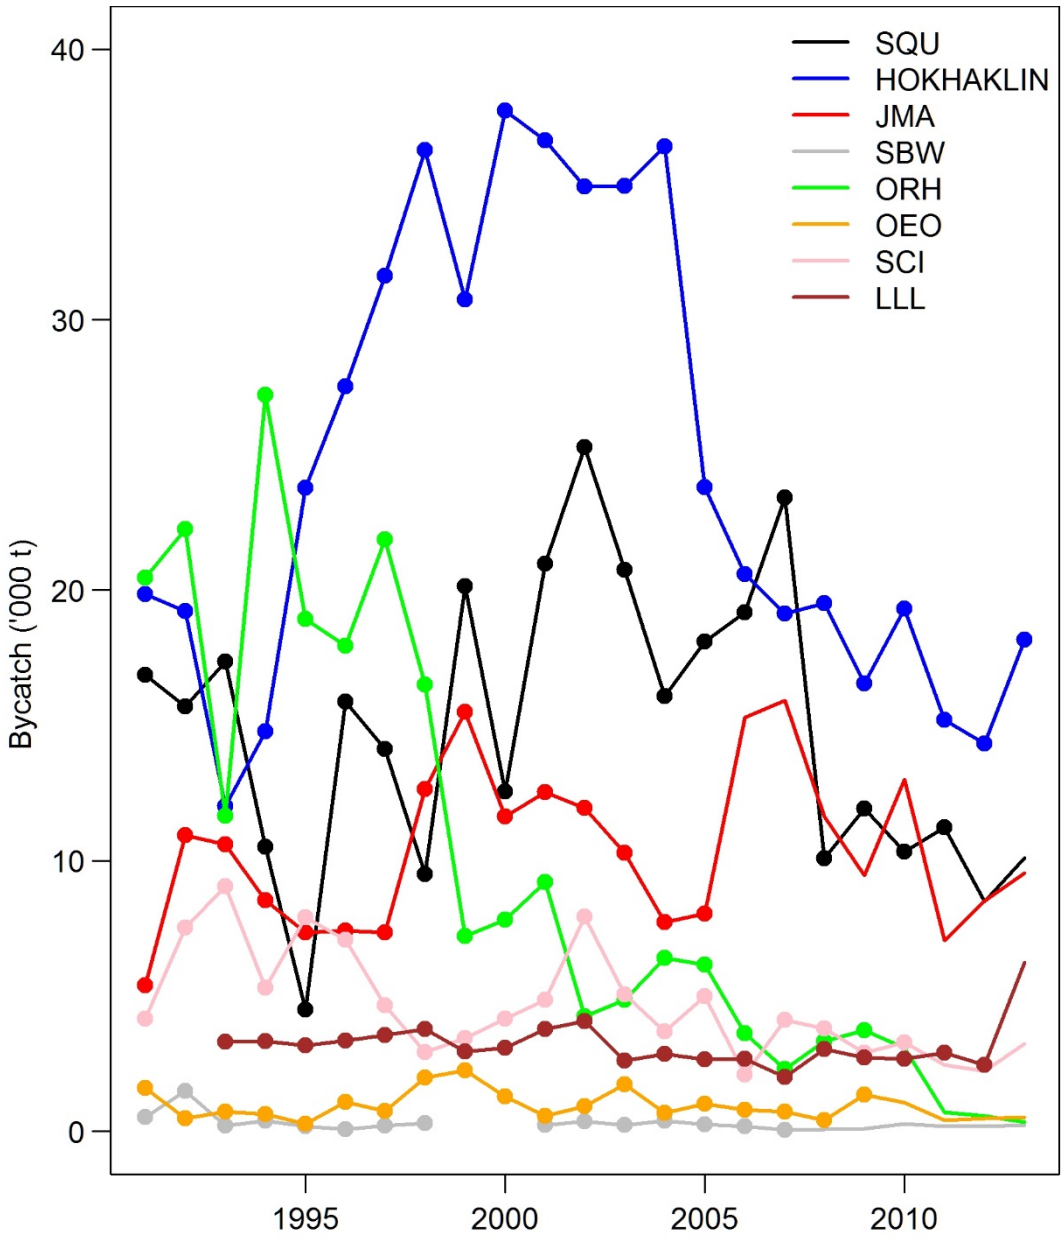

Figure 9a: Bycatch in all reported fisheries. (Dots are precision based estimates; no dots are coarse based estimates).

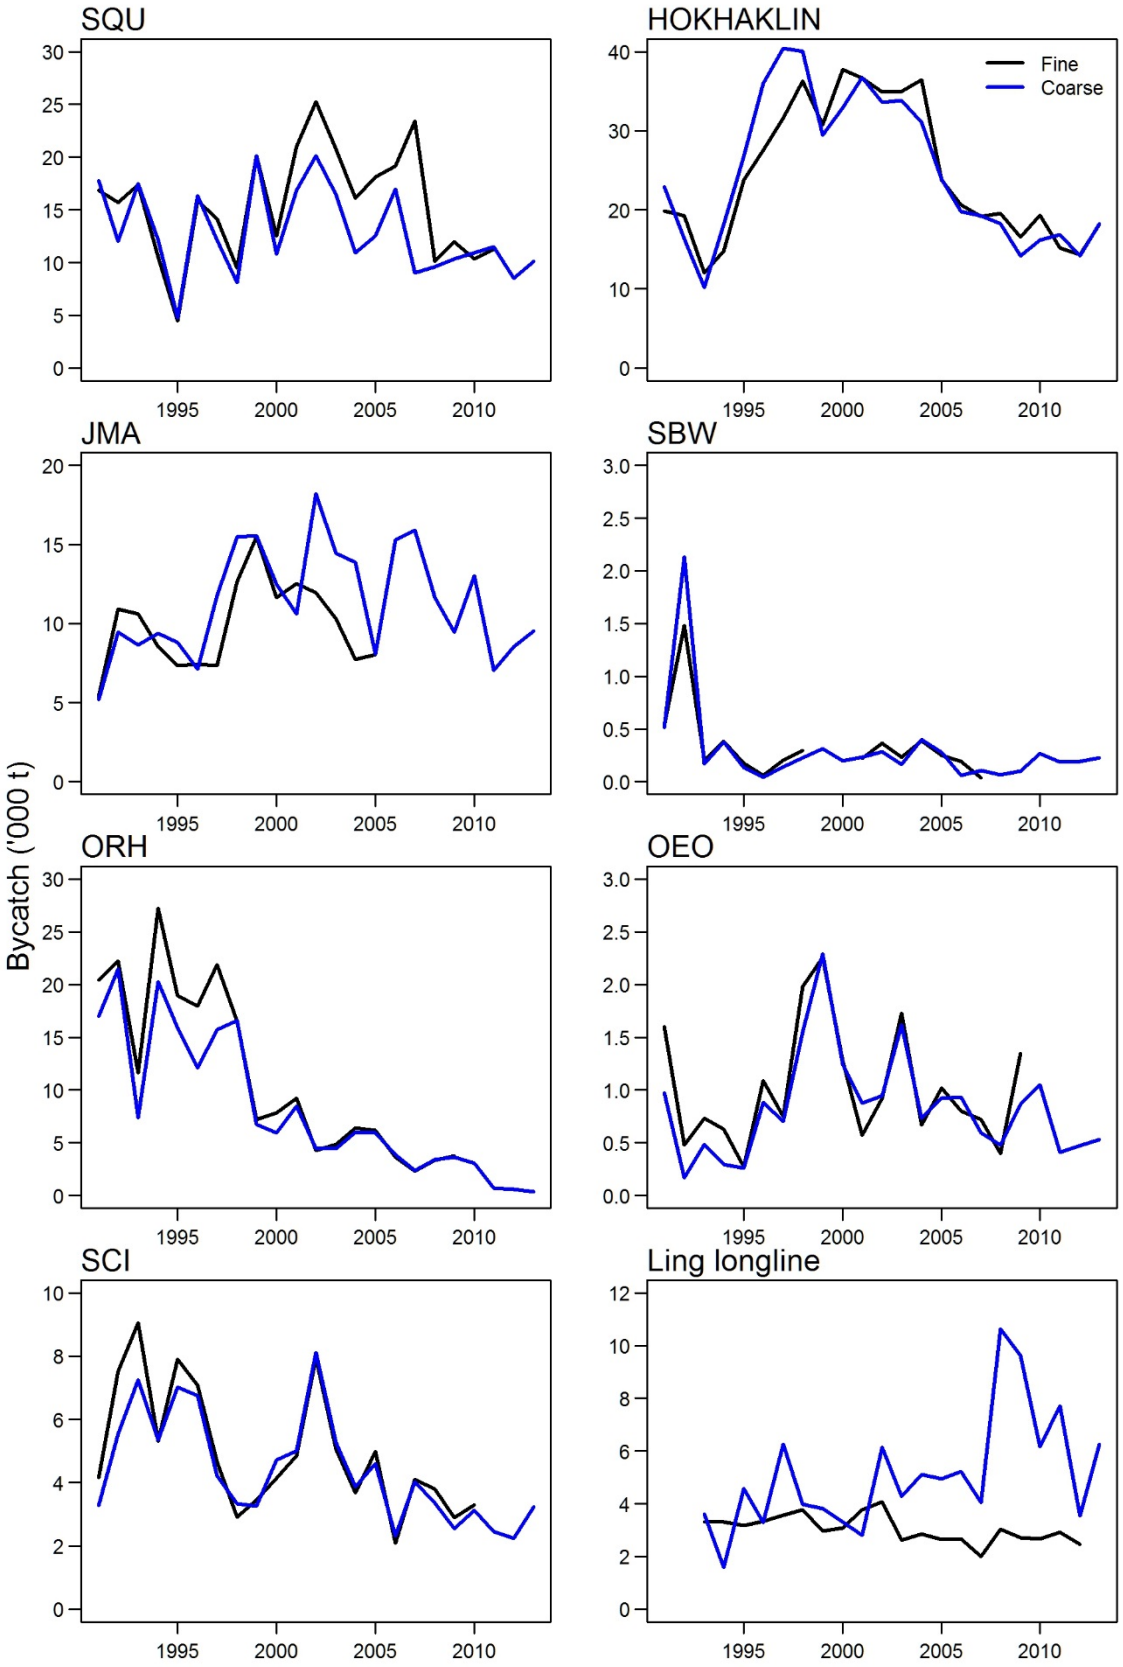

Figure 9b: A comparison of precision (black) and coarse (blue) based total bycatch estimates by fishing year in the main tier-1 deepwater fisheries.

ACKNOWLEDGMENTS

We would like to thank the observers of the Ministry for Primary Industries for their dedication and continued efforts over a long period to collect the high quality data that made this analysis possible. Thanks also to Owen Anderson (NIWA) for his review of the report, and Richard Ford (Ministry for Primary Industries) for valuable comments. This work was funded by the Ministry for Primary Industries (Project DAE20100D2).

Table 1b: Arrow squid trawl fishery. Total annual bycatch estimates (t) for individual species with at least 1 t of bycatch in at least one year for the 2011–12 and 2012–13 fishing years, based on observer catch rates; - means less than 1 t. (see http://marlin.niwa.co.nz **for species code definitions).**

Table 2: Hoki, hake, and ling trawl fishery. Total annual bycatch estimates (t) (with estimated CVs in parentheses where available—see text) for individual species, based on observer catch rates. Species are ordered by decreasing total catch. The slope of a regression through the data points is shown in parentheses alongside each species code. See http://marlin.niwa.co.nz **for species code definitions).**

Table 3: Jack mackerel trawl fishery. Total annual bycatch estimates (t) for individual species with at least 1 t of bycatch in at least one year, based on observer catch rates; - means less than 1 t. The slope of a regression through the data points is shown after fishing year (see http://marlin.niwa.co.nz for species code definitions).

Table 4a: Ling longline fishery. Total annual bycatch estimates (t) (with estimated CVs in parentheses) for individual species with at least 0.1 t of bycatch in at least one year, based on observer catch rates. Species are ordered by decreasing total catch. The slope of a regression through the data points is shown in parentheses alongside each species code. See http://marlin.niwa.co.nz for species code definitions). Data from Anderson (2014a).

Table 5: Orange roughy trawl fishery. Total annual bycatch estimates (t) for individual species with at least 1 t of bycatch in at least one year, based on observer catch rates; - means less than 1 t. The slope of a regression through the data points is shown after fishing year (see http://marlin.niwa.co.nz for species code definitions).

Table 6: Oreo trawl fishery. Total annual bycatch estimates (t) for individual species with at least 1 t of bycatch in at least one year, based on observer catch rates; - means less than 1 t. The slope of a regression through the data points is shown after fishing year (see http://marlin.niwa.co.nz for species code definitions).

Table 8: Southern blue whiting trawl fishery. Total annual bycatch estimates (t) for individual species with at least 1 t of bycatch in at least one year, based on observer catch rates; - means less than 1 t. The slope of a regression through the data points is shown after fishing year (see http://marlin.niwa.co.nz for species code definitions).

Table 9: Regression slopes for each species/species group and fishery, from Tables 1–8. Slopes indicating a decline in bycatch over time are highlighted in salmon, and slopes indicating an increase in bycatch over time are highlighted in blue. Species/species groups are ordered alphabetically; blank cells = not estimated; LLL = ling longline fishery; HHL = hoki/hake/ling fishery.
