## SPINY DOGFISH (SPD)

(Squalus acanthias)
Makohuarau, Pioke, Kāraerae

## 1. FISHERY SUMMARY

### 1.1 Commercial fisheries

Spiny dogfish are found throughout the southern half of New Zealand, extending to East Cape and Manakau Harbour on the east and west coasts of the North Island respectively. A related species, the northern spiny dogfish (Squalus mitsukurii), is mainly restricted to North Island waters, overlapping with its conspecific in the central west coast area and around the Chatham Islands. Although they have different species codes for reporting purposes it is probable that some misidentification and misreporting occurs-particularly in FMAs 1,8 , and 9.

The best estimate of reported catch from the fishery is shown in the final column in Table 1. For the period 1980-81 to 1986-87 the best estimate of landings is the sum of the FSU data. For the period 1987-88 to 1996-97 it is the sum of the LFRR and the discards from the CELR and CLR. It has been assumed here that all the fish which have been caught and discarded will die, and that all the discarded fish have been recorded. Although neither assumption is likely to be true, and the biases they produce will at least partially cancel each other out, it is likely that the true level of discards is considerably higher. However, these figures are currently the best estimates of total removals from the fishery from 1980-81 to 1996-97.

Before 1980-81 landings of rig and both Squalus species were included together and catches of the latter were probably small. Since then the reported landings of spiny dogfish has fluctuated between about 3000 and 7000 t in most years, averaging about 5600 t from 2010-11 to 2018-19. The reported catch by the deepwater fleet has remained fairly constant during most of the period, averaging 2000-4000 t, with a slight decrease in recent years. The reported catch by the inshore fleet has shown a steady increase throughout the period and is now at a similar level to the catch from the deepwater fleet.

Most of the spiny dogfish caught by the deepwater fleet are taken as a bycatch in the jack mackerel, barracouta, hoki, red cod, and arrow squid fisheries, in depths from 100 to 500 m . Some are packed whole but most are trunked and exported to markets in Asia and Europe.

Table 1: Reported catches of spiny dogfish (t) by fishing year. FSU (Fisheries Statistics Unit), LFRR (Licensed Fish Receiver Return). Discards reported from CELR (Catch Effort Landing Return), and CLR (Catch Landing Return). Numbers in brackets are probably underestimates. ( no data).

|  | FSU |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: |
|  | Inshore | Deepwater <br> 190 | LFRR | Discards | Best <br> Estimate |
| $1980-81$ | - | $(196)$ | - | - | 196 |

| $1995-96$ | - | - | 6230 | 1920 | 8150 |
| $1996-97$ | - | - | 4887 | 2572 | 7459 |

Spiny dogfish are also taken as bycatch by inshore trawlers, setnetters, and longliners targeting flatfish, snapper, tarakihi, and gurnard. Because of processing problems due to their spines, sandpaper-like skin, and short shelf life, and their low economic value, many inshore fishers are not interested in processing and landing them. Furthermore, because of their sheer abundance they can at times severely hamper fishing operations for other commercial species and they are regarded by many fishers as a major nuisance. Trawlers working off Otago during the summer months often reduce towing times and headline heights, and at times leave the area altogether to avoid having to spend hours pulling hundreds of meshed dogfish out of trawl nets. Setnetters and longliners off the Otago coast, and in Tasman Bay and the south Taranaki Bight, have also complained about spiny dogfish taking longline baits, attacking commercial fish caught in the nets or lines, and rolling up nets.

Table 2 gives available historical landings data for 1978 to 1982 . The catch by FMA from the FSU, CELR, and CLR databases is shown in Table 3. Substantial landings have been reported from FMAs 3, 5,6 , and 7 since 1982-83; landings from FMA 4 have increased substantially since the mid-1990s. In the early 1980s landings were highest in FMAs 5 and 6, with 1000-2000 $t$ taken annually by factory trawlers. By the 1990s landings from FMA 3 and, to a lesser extent, FMA 7 became more important. The catch in both these areas was taken equally by factory trawlers and inshore fleets. Since the fishing year 2013-14 the highest landings have been reported from SPD 3, 4, and 5, which together contributed $82 \%$ of total spiny dogfish landings in 2019-20. The catch in FMA 1 is unlikely to be spiny dogfish which is considered to be virtually absent from the area, and so these catches should probably be attributed to $S$. mitsukurii.

Table 2: Reported landings (t) for the main QMAs from 1978 to 1982. For SPD, there are no data available for 1931 to 1977 years.

| Year | SPD | SPD | SPD | SPD | SPD | SPD |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: |
|  | $\mathbf{1}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{7}$ | $\mathbf{8}$ |
| 1978 | 1 | 20 | 0 | 38 | 124 | 41 |
| 1979 | 2 | 130 | 67 | 74 | 128 | 40 |
| 1980 | 0 | 39 | 13 | 149 | 11 | 31 |
| 1981 | 2 | 123 | 92 | 203 | 73 | 150 |
| 1982 | 20 | 291 | 31 | 2228 | 113 | 84 |

[^0]Competitive quotas of 4075 t for FMA 3, and of 3600 t for FMAs 5 and 6, were introduced for the first time in the 1992-93 fishing year. These quotas were based on yields derived from trawl surveys using a method that is now considered obsolete, and harvest levels which are now considered unreliable. The reported catches exceeded the FMA 3 quota in 1997-98, 2000-01, and 2001-02 and the FMAs 5 and 6 quota in 2001-02.

Spiny dogfish was introduced into the QMS in October 2004. Catches and TACCs are shown in Table 4, and Figure 1 depicts historical landings and TACC values for the main SPD stocks. Landings for all Fishstocks have generally remained well below the TACC limits.

Prior to their introduction into the QMS, spiny dogfish were legally discarded at sea (provided that total catch was reported). Although discard rates increased dramatically through the 1990s (Table 5), this is believed to reflect a change in reporting practice rather than an increase in the proportion of catch discarded. Spiny dogfish were placed on Schedule 6 when they were introduced to the QMS.

Table 3: Reported landings (t) of spiny dogfish by FMA. Proportions by area have been taken from CELR and CLR and prorated to the best estimate from Table 1. Competitive quotas of 4075 t for FMA 3, and of 3600 t for FMAs 5 and 6, were introduced for the first time in the 1992-93 fishing year.

| Year | FMA 1 | FMA 2 | FMA 3 | FMA 4 | FMA 5 | FMA 6 | FMA 7 | FMA 8 | FMA 9 | FMA 10 | Other | Total |

### 1.2 Recreational fisheries

Spiny dogfish are caught by recreational fishers throughout their geographical range in New Zealand. They are mainly taken as bycatch when targeting other more valued species using rod and line and setnet. In many parts of New Zealand, spiny dogfish are regarded by recreational anglers as a pest, often clogging nets and taking baits from hooks. Estimates of recreational landings obtained from telephone-diary surveys in 199192 to 1993-94, 1996, and 1999-00 are given in Table 6.

Table 6: Number and weight of spiny dogfish harvested by recreational fishers by Fishstock from telephone-diary surveys. Surveys were carried out in different years in the MAF Fisheries regions: South in 1991-92, Central in 1992-93, North in 1993-94 (Teirney et al 1997), and nationally in 1996 (Bradford 1998) and 1999-00 (Boyd \& Reilly 2004). Survey harvests are presented as a range to reflect the uncertainty in the estimates.

| Fishstock | Survey | Number | CV\% | Harvest Range (t) | Point estimate (t) |

The harvest estimates provided by telephone-diary surveys between 1991 and 2001 are no longer considered reliable for various reasons. A Recreational Technical Working Group concluded that these harvest estimates should be used only with the following qualifications: a) they may be very inaccurate; b) the 1996 and earlier surveys contain a methodological error; and c) the 2000 and 2001 estimates are implausibly high for many important fisheries. In response to these problems and the cost and scale challenges associated with onsite methods, a national panel survey was conducted for the first time throughout the 2011-12 fishing year. The panel survey used face-to-face interviews of a random sample of 30390 New Zealand households to recruit a panel of fishers and non-fishers for a full year (WynneJones et al 2014). The panel members were contacted regularly about their fishing activities and harvest
information in standardised phone interviews. The national panel survey was repeated during the 201718 and 2022-23 fishing years using very similar methods to produce directly comparable results (Wynne-Jones et al 2019; Heinemann \& Gray, in prep). Recreational catch estimates from the three national panel surveys are given in Table 7. Note that national panel survey estimates do not include recreational harvest taken on charter vessel trips or under s111 general approvals.

### 1.3 Customary non-commercial fisheries

Māori fishers traditionally caught large numbers of 'dogfish' and this included rig, school shark, and spiny dogfish. Quantitative information on the current level of customary non-commercial fisheries take is not available.

### 1.4 Illegal catch

It is unlikely that there is an illegal catch of spiny dogfish because the quota for this species has never been reached, and it has low commercial value.

Table 7: Recreational harvest estimates for spiny dogfish stocks from national panel surveys (Wynne-Jones et al 2014, 2019, Heinemann \& Gray, in prep). Mean weights from boat ramp surveys (Hartill \& Davey 2015, Davey et al 2019; Davey et al in prep).

## 2. BIOLOGY

Spiny dogfish are widely distributed around the South Island and extend as far north as Manukau Harbour and East Cape on the west and east coasts of the North Island, respectively. They are most abundant off the east coast of the South Island and the Stewart-Snares shelf. They are found on the continental shelf and upper slope down to a depth of at least 500 m but are most common in depths of $50-150 \mathrm{~m}$. Schools are strongly segregated by size and sex. The size of fish in the commercial fishery is not known but will depend to a large extent on the method of capture and the area fished.

Spiny dogfish are born at a size of $18-30 \mathrm{~cm}$ total length (TL). They have been aged using fin spines, and early growth has been validated by following modes in length frequency and eye lens weight frequency data. Males mature at 58 cm TL at age 6, and females mature at 73 cm TL at age 10. The maximum ages and lengths in a study of east coast South Island dogfish were 21 years and 90 cm TL for males, and 26 years and 111 cm TL for females.
$M$ was estimated using the equation $\log _{\mathrm{e}} 100 /$ maximum age, where maximum age is the age to which $1 \%$ of the population survive in an unexploited stock. Using a maximum age of 26 gave an estimate of $M$ of 0.18. This has been revised up to 0.2 to reflect the imprecision with which this estimate is known. A similar estimate of $M$ was obtained using a survivorship table approach (Hanchet 1986). At an instantaneous mortality rate of $0.2 \mathrm{y}^{-1}$ an initial population of 1000 females would replace themselves over their lifespan (given their length-at-age, length-at-maturity, and fecundity-length relationships).

Female spiny dogfish give birth to young over an extended period between April and September, mainly on the shelf edge in depths of 200-300 m . Mating also occurs in deeper water (coincident with a movement of mature males offshore), after which females with young 'candled' embryos move into shallower waters of 100 m or less. They remain there for 12 months until the embryos are 15 cm long after which they return to deeper water. Parturition occurs after a gestation period approaching 24 months, and this is closely followed by mating and ovulation and the biennial cycle is repeated. Both the number and the size of the young increase linearly with the length of the mother. The number of young per litter ranges from 1 to 19 .

Young of the year move inshore into shallower waters shortly after birth. Over the next few years they move steadily into deeper water but remain in size segregated schools comprising up to 2 or 3 age classes. Once maturity is reached both males and females undergo inshore/offshore migrations associated with reproductive activity. A north/south migration along the east coast South Island during autumn/spring has also been postulated, but the full extent of this migration is unknown.

Spiny dogfish are found both on the bottom and in midwater and feed on a very wide range of species, including Munida, krill, fish, squid, and crabs.

Biological parameters relevant to the stock assessment are shown in Table 8.
Table 8: Estimates of biological parameters of spiny dogfish for QMA 3 (Hanchet 1986).

## 3. STOCKS AND AREAS

No specific research on the stock structure of spiny dogfish has been carried out. Limited tagging has been conducted, so the only available data come from seasonal trawl surveys and fisheries landings data.

The analysis of W.J. Scott and James Cook surveys carried out from 1978 to 1983 clearly showed seasonal migrations of spiny dogfish along the east coast of South Island (ECSI). Spiny dogfish were most abundant in the southern part of the coast from October to April, and more abundant to the north in May to September. It is also clear from summer trawl surveys of the area that there is a resident part of the population of spiny dogfish on the Stewart-Snares shelf over the summer months. However, there have been no comparable series of seasonal surveys there and so it is presently unclear whether the east coast South Island fish migrate south as far as the Stewart-Snares shelf. Until more data become available fish from the two areas should be treated as separate stocks.

Seasonal trawl surveys were also carried out off west coast South Island (WCSI) between June 1981 and April 1983 using the W.J. Scott. The catches showed a strong seasonal component being highest in summer and autumn and lowest in winter and spring. It is likely that some fish migrate north in winter, perhaps to the northern and southern Taranaki Bights, and Tasman Bay and Golden Bay. However, it is also clear from summer trawl surveys of the areas that there is a resident part of the population of spiny dogfish in the Taranaki Bights over the summer months. It may therefore be appropriate to treat fish from FMAs 7 and 8 as a single stock.

There is little commercial catch in FMAs 1, 2, 4, and 9, and little data on movement in or between the areas. Until more data have been obtained it would seem appropriate to manage spiny dogfish with the following five fishstocks:

- SPD 1: FMAs 1 \& 2
- SPD 3: FMA 3
- SPD 4: FMA 4
- SPD 5: FMAs 5 \& 6
- SPD 7 and SPD 8: FMAs 7, 8, \& 9

## 4. STOCK ASSESSMENT

There are no estimates of current or virgin biomass.

### 4.1 Estimates of fishery parameters and abundance

Biomass indices of spiny dogfish from recent trawl surveys using Tangaroa and Kaharoa are summarised in Figures $2-5$ and Table 9. Based on a combination of CVs, variability in biomass indices, and the time span of each series, it is concluded that surveys provide reliable indices of dogfish abundance off the west coast of the South Island, the east coast of the South Island, and on the Chatham Rise. Relative biomass indices suggest that spiny dogfish became more abundant on the Chatham Rise during the early to mid-1990s. Apart from a temporary increase during the mid-1990s, the abundance of spiny dogfish off the west coast South Island appears to have been fairly stable. Off the east coast of the South Island spiny dogfish biomass increased in the early 1990s and since 2007 when these surveys were reinstated, has been generally been declining.

## West coast South Island inshore trawl survey

Biomass fluctuated between 3919 and 10270 t from 1992 to 2011 (Table 9, Figure 2). Biomass in 2013 was the highest in the series, but this was influenced by a single large catch, reflected in the large CV. Biomass has generally declined since then to the lowest estimate of the series in 2021 at 2226 t . While there was a slight increase in 2023 to 3043 t , the last four estimates of the series were the lowest. The increase in biomass came from Tasman Bay and Golden Bay and the west coast (MacGibbon et al. 2024). Throughout the time series, more biomass has come from the west coast, but biomass has been more stable in Tasman Bay and Golden Bay. This decline in abundance was also present in other surveys, including the more offshore west coast South Island trawl survey carried out on RV Tangaroa (Devine et al. 2022) and the winter inshore east coast South Island survey (MacGibbon et al. 2019, Beentjes et al. 2022).

The length frequency has shown a fairly broad distribution for spiny dogfish from the west coast over time, usually between about 30 cm and 80 cm (MacGibbon et al. 2024). The length frequency distribution for Tasman Bay and Golden Bay has been narrower in comparison with the west coast, mainly from about $50-70 \mathrm{~cm}$, and comprised mostly of males. From about 2013, both the left- and right-hand tails of the west coast distribution have been truncated. This was not so apparent in the Tasman Bay and Golden Bay distribution.

In most years, adult fish have made up most of the biomass, with exceptions in 2019 and 2023 (MacGibbon et al. 2024). The juvenile contribution to biomass was still a significant proportion, especially when compared with most other species monitored by the survey. The small increase in biomass in 2023 came from both juvenile and adult fish but mainly from juveniles.

Figure 2: Spiny dogfish biomass for the west coast South Island inshore trawl survey time series (error bars are $\pm$ two standard deviations).

## Chatham Rise trawl survey

The Chatham Rise trawl survey was designed primarily for hoki and, for spiny dogfish, covers the relevant depth range 200-400 m . It therefore excludes a small portion of SPD habitat at depths less than 200 m around the Mernoo Bank and Chatham Islands. The survey biomass estimates for SPD increased from 1992 to 1997 and have cycled around the series mean since then (Figure 3). The Chatham Rise SPD survey catch is dominated by mature females ( $60-100 \mathrm{~cm}$ ), whereas that of the ECSI survey consists mostly of males and females $<60 \mathrm{~cm}$ (Beentjes et al 2016, Stevens et al 2015).

Figure 3: Spiny dogfish biomass for the Chatham Rise inshore trawl survey time series (error bars are $\pm$ two standard deviations).

## East coast South Island inshore trawl survey

The east coast South Island winter surveys from 1991 to 1996 ( $30-400 \mathrm{~m}$ ) were replaced by summer trawl surveys (1996-97 to $2000-01$ ) which also included the $10-30 \mathrm{~m}$ depth range; but these were discontinued after the fifth in the annual time series because of the extreme fluctuations in catchability between surveys (Francis et al 2001). The winter surveys were reinstated in 2007, and this time were expanded to include the $10-30 \mathrm{~m}$ depth range, to monitor elephantfish and red gurnard which were officially included in the list of target species in 2012. Seven surveys (2007, 2012, 2014, 2016, 2018, 2021 , and 2022) surveys The 2007 survey and all surveys from 2012 onward provide full coverage of the $10-30 \mathrm{~m}$ depth range.

Spiny dogfish biomass in the core survey area increased markedly in 1996 and has fluctuated over the last eight surveys with a clear declining trend, to the lowest observed level in 2021, followed by a more than three-fold increase in 2022 (Table 9, Figure 4) (Beentjes et al in press). Pre-recruited biomass was a small component of the total biomass estimate in the 1992 to 1994 surveys at $1-3 \%$ of total biomass, but since 1996 it has ranged from 7 to $52 \%$, and, in 2022, it was $15 \%$, similar to the post-1994 average of $19 \%$ (Table 9, Figure 4). This is also reflected in the biomass of juvenile spiny dogfish (based on the length-at$50 \%$ maturity), which increased markedly from about $14 \%$ of total biomass before 1996 to between 32 and $63 \%$ in the last ten surveys, and in 2022 it was $47 \%$.

The additional spiny dogfish biomass captured in the $10-30 \mathrm{~m}$ depth range accounted for, on average, $8 \%$ of the biomass in the core plus shallow strata ( $10-400 \mathrm{~m}$ ) with a range of $5-13 \%$, and, in 2022, it was $12 \%$, indicating that it is useful to monitor the shallow strata for spiny dogfish biomass (Table 9, Figure 4). The addition of the $10-30 \mathrm{~m}$ depth range had little effect on the shape of the spiny dogfish length frequency distributions with the exception of 2022, when the smallest fish were caught in less than 30 m . The spatial distribution of spiny dogfish hotspots varies, but overall this species is consistently well represented over the entire survey area, most commonly from 30 m to about 350 m . Spiny dogfish are consistently the most commonly caught species on the ECSI trawl survey and occurred in $94-100 \%$ of core strata tows with no trend ( $98 \%$ in 2022). Spiny dogfish comprised $10-46 \%$ of the total catch on the surveys with a downward trend until 2021, before increasing again in 2022 to $27 \%$, which was also the average of all surveys.

The size distributions of spiny dogfish in the 1992 to 1994 surveys were similar and generally bimodal for males, but less defined for females which are less numerous than males with more females over 80 cm , throughout the core strata time series. From 1996 onwards, smaller fish were more abundant, and there were many more larger fish in the population. The large increase in biomass observed post-1996 is in part a result of the change in the population size composition. In contrast, in 2021 the time series biomass low is associated with a marked drop-off in numbers of larger fish over about 50 cm , which subsequently reappeared in 2022, concurrent with the three-fold biomass increase. Spiny dogfish on the ECSI sampled on these surveys were considerably smaller than those from the Chatham Rise, Southland, and the subAntarctic surveys (Bagley \& Hurst 1996, O’Driscoll \& Bagley 2001, Stevens et al 2021, 2022 ), suggesting that this area may be an important nursery ground for juvenile spiny dogfish and there may be movement in and out of the ECSI survey area.

Survey year
Figure 4: Spiny dogfish total biomass for ECSI winter surveys in core strata ( $\mathbf{3 0 - 4 0 0} \mathbf{~ m}$ ), and core plus shallow strata ( $10-\mathbf{4 0 0} \mathbf{~ m}$ ). Error bars are $\pm$ two standard deviations.
 Stewart-Snares shelf, Sub-Antarctic, west coast South Island (WCSI) and west coast North Island (WCNI) survey areas*. Biomass estimates for ECSI in 1991 have been adjusted to allow for non-sampled strata ( $7 \& 9$ equivalent to current strata 13,16 , and 17 ). The sum of pre-recruit and recruited biomass values do not always match the total biomass for the earlier surveys because at several stations length frequencies were not measured, affecting the biomass calculations for length intervals. - , not measured; NA, not applicable. Recruited is defined as the size-at-recruitment to the fishery ( 50 cm ). [Continued on next two pages]

Table 9 [Continued]: Relative biomass indices (t) and coefficients of variation (CV) for spiny dogfish for east coast North Island (ECNI), east coast South Island (ECSI) - summer and winter, Chatham Rise, Stewart-Snares shelf, Sub-Antarctic, west coast South Island (WCSI) and west coast North Island (WCNI) survey areas*. Biomass estimates for ECSI in 1991 have been adjusted to allow for non-sampled strata ( $7 \& 9$ equivalent to current strata 13,16 , and 17 ). The sum of pre-recruit and recruited biomass values do not always match the total biomass for the earlier surveys because at several stations length frequencies were not measured, affecting the biomass calculations for length intervals. - , not measured; NA, not applicable. Recruited is defined as the size-at-recruitment to the fishery ( $\mathbf{5 0} \mathbf{~ c m}$ ).

*Assuming areal availability, vertical availability, and vulnerability equal 1.0. Biomass is only estimated outside 10 m depth except for COM9901 and CMP0001. Note: because trawl survey biomass estimates are indices, comparisons between different seasons (e.g., summer and winter ECSI) are not strictly valid.

Manning et al (2004) evaluated the usefulness of commercial CPUE, commercial length composition, trawl survey relative biomass estimates and trawl-survey-catch length composition for monitoring all major SPD stocks (Table 10).

Table 10: Catch and effort data sets and analyses evaluated as monitoring tools for major SPD stocks.

```
QMA
SPD 3 - East coast South Island
SPD 4-Chatham Rise
SPD 5 - Stewart-Snares shelf
SPD 7 - West coast South Island
```

## Data set and analysis

1. Standardised setnet CPUE for core vessels targeting SPD.

Standardised setnet CPUE for core vessels targeting all species.
Standardised bottom trawl CPUE for core vessels targeting all species.
Relative abundance indices from east coast South Island trawl surveys (discontinued after 2001).
Standardised bottom trawl CPUE for core Korean vessels.
Standardised bottom trawl CPUE for core domestic vessels.
Standardised bottom longline CPUE for core domestic vessels
Relative abundance indices from Chatham Rise trawl surveys.
9. Standardised bottom trawl CPUE
10. Relative abundance indices from Stewart-Snares shelf surveys (discontinued after 1996).
11. Standardised bottom trawl CPUE for core vessels.
12. Relative abundance indices from west coast South Island trawl surveys.

Based on the results of the analyses listed in Table 10, the following methods were recommended for monitoring SPD:

## QMA

SPD 3 - East coast South Island
SPD 4 - Chatham Rise
SPD 5 - Stewart-Snares shelf
SPD 7 - West coast South Island

Recommended Monitoring Tools
Standardised setnet CPUE using model 2 (core vessels targeting all species)
Chatham Rise trawl survey and length composition of commercial catch
*Standardised bottom trawl CPUE and length composition of commercial catch
West coast South Island trawl survey and length composition of commercial catch
is required before this index can be used

### 4.2 Biomass estimates

Lack of suitable information has precluded estimation of virgin and current biomass for spiny dogfish. Although most of the necessary biological parameters (Hanchet 1986, 1988, Hanchet \& Ingerson 1997), relative indices of abundance and data required to estimate fishing selectivity for most important fisheries (with the exception of FMA 4 bottom longline and FMA 3 setnet fisheries) are now available, robust stock assessments will also require estimates of historical, unreported discarding and discard mortality so that an accurate history of fishery related removals can be constructed.

### 4.3 Yield estimates and projections

$M C Y$ cannot be estimated.
$C A Y$ cannot be determined.

### 4.4 Other factors

The ability to withstand harvesting depends on the strength of a number of compensatory mechanisms. For example, under exploitation individuals may grow faster, show increased fecundity, or suffer reduced natural mortality. In elasmobranchs the number of young born is related directly to the number of adult females, and, because of the relatively large size and hence good survival of the young at birth, it is presumed that there is a strong stock recruit relationship for these species.

Several methods of estimating $M C Y$ involve the multiplication of a harvest level by an estimate of $B_{0}$ or $B_{a v}$. Francis \& Francis (1992) used Monte Carlo simulation to estimate harvest levels for calculating MCY for a rig stock. No stock-recruitment data were available for elasmobranchs at the time and so they used values for the Beverton \& Holt steepness parameter ranging from 0.35 to 0.50 , and recruitment variability of 0.4 . These values were all at the low range of values used for teleost species and which they considered appropriate for rig. The results of their simulation studies showed that the estimates of $M C Y$ obtained using the harvest levels given in the equations in the Guide to Biological Reference Points were overly optimistic for rig. Given that spiny dogfish have a slower growth rate and are less fecund than rig, it seems reasonable to assume that those harvest levels are also unsuitable for spiny dogfish.

A data informed qualitative risk assessment was completed on all chondrichthyans (sharks, skates, rays and chimaeras) at the New Zealand scale in 2014 (Ford et al 2015). Spiny dogfish was ranked seventh highest in terms of risk of the eleven QMS chondrichthyan species. Data were described as existing and
sound for the purposes of the assessment and consensus over this risk score was achieved by the expert panel. This risk assessment does not replace a stock assessment for this species but may influence research priorities across species.

## 5. STATUS OF THE STOCKS

No estimates of current or reference biomass are available, but trawl survey estimates of abundance have been calculated for a number of years (Table 9).

Although reported commercial catches of spiny dogfish were observed to increase in all major FMAs during the 1990s, the extent to which these increases can be attributed to changes in reporting practice (i.e., more accurate reporting of discards in recent times) is uncertain. Trawl surveys, on the other hand, indicate that there was a general increase in the abundance of spiny dogfish, particularly around the South Island, in the mid-1990s.
