

DARK GHOST SHARK (GSH)

(*Hydrolagus novaezealandiae*)

1. FISHERY SUMMARY

(a) Commercial fisheries

Two species (dark and pale ghost sharks) make up virtually all the commercial ghost shark landings. Dark ghost shark (*Hydrolagus novaezealandiae*) was introduced into the QMS from the beginning of the 1998–99 fishing year for the 10 FMAs shown above.

Both ghost shark species are taken almost exclusively as a bycatch of other target trawl fisheries. In the 1990s, about 43% of ghost sharks were landed as a bycatch of the hoki fishery, with fisheries for silver warehou, arrow squid and barracouta combining to land a further 36%. The two ghost shark species were seldom differentiated on catch landing returns prior to the start of the 1998–99 fishing year. Estimated landings of both species by foreign licensed and joint venture vessels over the period 1 April 1978 to 30 September 1983 are presented in Table 1. Landings by domestic (inshore) vessels would have been negligible during this time period. The unknown quantities of ghost sharks that were discarded and not recorded are likely to have resulted in under-reported total catches over the full period for which data are available.

Commercial landings of ghost sharks have been made in FMAs 1–9. In the early to mid 1980s about half of the reported ghost shark landings were from FMA 3. Virtually all the additional catch was spread over FMAs 4–7. Landings have tended to increase over time. In 1988–89, landings from west coast South Island (FMA 7) began to increase, almost certainly associated with the development of the hoki fishery. This trend has accelerated in recent years. In 1990–91, significant landings increases were apparent on the Chatham Rise, off southeast South Island and on the Campbell Plateau. The development of fisheries for non-spawning hoki was probably responsible for these increases.

Estimated landings of dark ghost shark by QMA are shown in Table 2. Landings from 1983–84 to 1994–95 were derived by splitting all reported ghost shark landings into depth and area bins, and allocating to species based on distribution data derived from trawl surveys (see section 2). Landings from 1995–96 to 1998–99 were estimated assuming dark ghost shark made up 70% of the total ghost shark catch in FMAs 5 and 6, and 75% in all other FMAs.

Table 1: Reported landings (t) of both ghost shark species by fishing year and EEZ area, taken by foreign licensed and joint venture vessels. An approximation of these areas with respect to current QMA boundaries is used to assign catches to QMAs. No data are available for the 1980–81 fishing year.

* FSU data.

QMS data.

The TACs currently applied to dark ghost shark were initially intended to apply to a combined fishery for both species, and were based on average catches of both species over various periods (see the “Review of Sustainability Measures and Other Management Controls for the 1998–99 Fishing Year – Final Advice Paper” dated 6 August 1998). No allowance for non-commercial interests was included in the final allocation because recreational and Maori customary catches are likely to be very small due to the depth distribution of this species.

(b) Recreational fisheries

Current catches of dark ghost sharks by recreational fishers are believed to be negligible in all areas.

(c) Maori customary fisheries

Quantitative information on the current level of Maori customary take is not available.

(d) Illegal catch

Quantitative information on the level of illegal catch is not available. In 1998–99 (when dark ghost shark were in the QMS, but pale ghost shark were not), a quantity of dark ghost shark were reported as pale ghost shark.

(e) Other sources of mortality

Ghost sharks have been dumped and not reported in the past by commercial fishers in QMAs 1 and 2. Similar behaviour is believed to occur in all other QMAs. The extent of the unreported dumping is unknown in all areas.

2. BIOLOGY

Dark ghost shark (*Hydrolagus novaezelandiae*) occur through much of the New Zealand EEZ in depths from 30 to 850 m, but they are sparse north of 40° S and have not been recorded from the Bounty Platform. They are most abundant in waters 150–500 m deep on the west coast of the South Island and the Chatham Rise, and in depths of 150–700 m on the Stewart-Snares shelf and Southland/Sub-Antarctic. Smaller sharks (< 40 cm CL) are more abundant in waters shallower than 200 m, particularly in the Canterbury Bight.

Trawl surveys show that dark and pale ghost shark exhibit niche differentiation, with water depth being the most influential factor, although there is some overlap of habitat. On the Chatham Rise, the main overlap range appears quite compact (from about 340 to 540 m). In the Southland/Sub-Antarctic region, the overlap range is wider (about 350 to 770 m). Stomach contents indicate that both species are predominantly benthic feeders.

No published information is available on the age or growth rate of any *Hydrolagus* species, or even any species in the family Chimaeridae. Length-frequency histograms indicate that females grow to a larger size (and presumably have a faster growth rate) than males. Without population age structures or confident estimates of longevity, it is not possible to estimate natural or total mortalities. A recent study has shown that eye lens measurements and spine band counts are potentially useful ageing techniques for dark ghost sharks (Francis and Ó Maolagáin, 2001). However, these techniques have yet to be validated.

On the Chatham Rise, the estimated size at 50% sexual maturity for dark ghost sharks is 52–53 cm for males and 62–63 cm for females. As for most other elasmobranchs, ghost shark fecundity is likely to be low.

Biological parameters relevant to the stock assessment are shown in Table 3.

Table 3: Estimates of biological parameters for dark ghost shark, from Horn (1997).

FMA	Estimate	
	a	b
1. Weight = a (length) ^b (Weight in g, length in cm chimaera length)		
Dark ghost shark		
3 & 4	0.00202	3.274
5 & 6	0.00192	3.297

3. STOCKS AND AREAS

The only information which may indicate a stock boundary is an apparent difference in maximum size of dark ghost sharks, with both males and females from the Chatham Rise attaining a maximum size 3–4 cm greater than those in Southland/Sub-Antarctic waters.

Horn (1997) proposed that dark ghost sharks be managed as three Fishstocks, i.e., east coast New Zealand (FMAs 1–4), Stewart-Snares shelf and Campbell Plateau (FMAs 5 and 6), and west coast New Zealand (FMAs 7, 8, and 9). Areas of narrow continental shelf separate these FMA groupings, so they could well provide barriers to stock mixing.

4. STOCK ASSESSMENT

No assessment of any stocks of dark ghost shark has been completed. Therefore, no estimates of yield are available.

(a) Estimates of fishery parameters and abundance

Estimates of fishery parameters are not available for dark ghost sharks. Several time series of relative biomass estimates are available from trawl surveys (Table 4), but wide fluctuations between years suggest the need for caution in using these as indicators of relative abundance. Longer time series may ultimately prove useful.

(b) Biomass estimates

No biomass estimates are available for dark ghost shark.

(c) Estimation of Maximum Constant Yield (MCY)

Because no estimates of biomass and harvest rates are available, the only possible method of calculating maximum constant yield is $MCY = cY_{av}$ (Method 4). However, it was decided that no estimates of MCY would be presented because:

- i. M (and hence, the natural variability factor c) is unknown,
- ii. the level of discarding is unknown and may have been considerable, and
- iii. no sufficiently long period of catches was available where there were no systematic changes in catch or effort (noting that the period of catches from which Y_{av} is derived should be at least half the exploited life span of the fish).

(d) Estimation of Current Annual Yield (CAY)

In the absence of estimates of current biomass, CAY has not been estimated.

(e) Other yield estimates and stock assessment results

No other yield estimates are available.

(f) Other factors

Elasmobranchs are believed to have a strong stock-recruit relationship; the number of young born is related directly to the number of adult females. Ghost shark fecundity is unknown, but is probably low. Assuming a strong stock-recruit relationship, Francis & Francis (1992) showed that the estimates of MCY obtained using the equations in current use in New Zealand stock assessments were overly optimistic for rig, and it is likely that they are also unsuitable for ghost sharks.

5. STATUS OF THE STOCKS

No estimates of current and reference biomass are available for dark ghost shark.

While inshore trawl surveys have generally exhibited a trend of increasing dark ghost shark biomass, the more comprehensive middle depths surveys produced wide fluctuations in estimated biomass.

Reported landings from this fishery have been increasing in recent years, probably owing to both an increased level of catch and to more accurate reporting. It is not known if recent catch levels or current TACCs are sustainable in the long term or whether they will allow the stocks to move towards a size that will support the maximum sustainable yield.

Summary of TACCs (t) and reported landings (t) for dark ghost shark for the most recent fishing year.

Fishstock	QMA	2004-05	2004-05
