

## PALE GHOST SHARK (GSP)

(*Hydrolagus bemisi*)

### 1. FISHERY SUMMARY

#### (a) Commercial fisheries

Two species (dark and pale ghost sharks) make up virtually all the commercial ghost shark landings. Pale ghost shark (*Hydrolagus bemisi*) was introduced into the QMS from the beginning of the 1999–00 fishing year as 3 Fishstocks: GSP 1 – QMAs 1 to 4, and 10; GSP 5 – QMAs 5 and 6 and GSP 7 – QMAs 7, 8 and 9.

Both ghost shark species are taken almost exclusively as a bycatch of other target trawl fisheries. In the 1990s, about 43% of ghost sharks were landed as a bycatch of the hoki fishery, with fisheries for silver warehou, arrow squid and barracouta combining to land a further 36%. The two ghost shark species were seldom differentiated on catch landing returns prior to the start of the 1998–99 fishing year. Estimated landings of both species by foreign licensed and joint venture vessels over the period 1 April 1978 to 30 September 1983 are presented in Table 1. Landings by domestic (inshore) vessels would have been negligible during this time period. The unknown quantities of ghost sharks that were discarded and not recorded are likely to have resulted in under-reported total catches over the full period for which data are available.

Commercial landings of ghost sharks have been made in QMAs 1–9. In the early to mid 1980s, about half of the reported ghost shark landings were from QMA 3. Virtually all the additional catch was spread over QMAs 4–7. Landings have tended to increase over time. In 1988–89, landings from west coast South Island (QMA 7) began to increase, almost certainly associated with the development of the hoki fishery. This trend has accelerated in recent years. In 1990–91, significant landings increases were apparent on the Chatham Rise, off southeast South Island, and on the Campbell Plateau. The development of fisheries for non-spawning hoki was probably responsible for these increases.

**Table 1: Reported landings (t) of both ghost shark species by fishing year and EEZ area, taken by foreign licenced and joint venture vessels. An approximation of these areas with respect to current QMA boundaries is used to assign catches to QMAs. No data are available for the 1980–81 fishing year.**

Year	QMA	EEZ Area											Total
		B 1&2	C(M) 3	C(1) 4	D	E(B) 5	E(P) 6	E(C) 6	E(A) 5	F(E) 5	F(W) 7	G 8

\* April 1 to March 31.

# April 1 to Sept 30.

Estimated landings of pale ghost shark by QMA are shown in Table 2. Landings from 1983–84 to 1994–95 were derived by splitting all reported ghost shark landings into depth and area bins, and allocating to species based on distribution data derived from trawl surveys (see section 2). Landings from 1995–96 to 1998–99 were estimated assuming pale ghost shark made up 30% of the total ghost shark catch in QMAs 5 and 6, and 25% in all other QMAs.

From 1 Oct 1999 TACCs were set for pale ghost shark fishstocks as follows: GSP 1 – 509 t, GSP 5 – 118 t and GSP 7 – 176 t. The TAC in each case was set equal to the TACC. Estimated and reported landings for this period are shown in Table 3. The fisheries in GSP1 and GSP5 exceeded the TACC by large amounts, possibly as a result of better reporting of catches. From 1 October 2004 the TACCs for GSP 1 and GSP 5 were increased to 1150 t and 454 t respectively, the level of catch being reported from the fisheries. Catches have since declined to well below the TACC levels.

In GSP 1, catches are mainly taken on the Chatham Rise while in GSP 5 catches are mainly taken in the Sub-Antarctic area; both as bycatch of the hoki trawl fisheries. Estimated catches appear to have been under-reported both before and after the introduction to the QMS. The original TACCs were based on estimated catches, but these are likely to have been much lower than the actual catches. Estimated catches on TCEPR forms since 1999–2000 were only 25–30% of the QMR totals. Trawl surveys of the Chatham Rise and Sub-Antarctic since 1992 show no change in abundance of pale ghost shark and recent surveys suggest good recruitment of small pale ghost shark.

**Table 2: Estimated landings (t) of pale ghost shark by fishery management area for fishing years 1982–83 to 1998–99 based on the reported landings of both species combined. The estimated landings up to 1994–95 are based on data in the 1997 Plenary Report. Landings from 1995–96 to 1998–99 were estimated assuming pale ghost shark made up 30% of the total ghost shark catch in QMAs 5 and 6, and 25% in all other QMAs.**

	QMA										Total

2004–05	565	1150	134	454	9	176	708	1780

**(b) Recreational fisheries**

Current catches of ghost sharks by recreational fishers are believed to be negligible in all areas.

**(c) Maori customary fisheries**

Quantitative information on the current level of Maori customary take is not available.

**(d) Illegal catch**

Quantitative information on the level of illegal catch is not available. In 1998–99 (when dark ghost shark were in the QMS, but pale ghost shark were not), a quantity of dark ghost shark were reported as pale ghost shark.

**(e) Other sources of mortality**

Ghost sharks have been dumped and not reported in the past by commercial fishers in QMAs 1 and 2. Similar behaviour is believed to occur in all other QMAs. The extent of the unreported dumping is unknown in all areas.

**2. BIOLOGY**

Pale ghost shark occur throughout the EEZ and have been recorded in depths ranging from 270 to 1200 m. They are most abundant in depths of 400–1000 m on the Chatham Rise and Southland/Sub-Antarctic, but are uncommon north of 40° S and appear to inhabit a narrower depth range in that region (600–950 m).

Trawl surveys show that dark and pale ghost shark exhibit niche differentiation, with water depth being the most influential factor, although there is some overlap of habitat. On the Chatham Rise, the main overlap range appears quite compact (from about 340 to 540 m). In the Southland/Sub-Antarctic region, the overlap range is wider (about 350 to 770 m). Stomach contents indicate that both species are predominantly benthic feeders.

No published information is available on the age or growth rate of any *Hydrolagus* species, or even any species in the family Chimaeridae. Length-frequency histograms indicate that females grow to a larger size (and presumably have a faster growth rate) than males. Hard parts of pale ghost shark have not yet been examined to check the existence of any banding pattern that may represent annual growth zones. Without population age structures or confident estimates of longevity it is not possible to estimate natural or total mortalities. A recent study has shown that eye lens measurements and spine band counts are potentially useful ageing techniques for dark ghost sharks (Francis & Ó Maolagáin, 2001). However, these techniques have yet to be validated.

On the Chatham Rise, the estimated size at 50% sexual maturity for pale ghost sharks is 59–60 cm for males and 69–70 cm for females. As for most other elasmobranchs, ghost shark fecundity is likely to be low.

Biological parameters relevant to the stock assessment are shown in Table 4.

**Table 4: Estimates of biological parameters for pale ghost shark, from Horn (1997).**

FMA	Estimate	
	a	b
1. Weight = a (length) <sup>b</sup> (Weight in g, length in cm chimaera length)		
Pale ghost shark		
3 & 4	0.00512	3.037
5 & 6	0.00946	2.883

### 3. STOCKS AND AREAS

Horn (1997) proposed that ghost sharks be managed as three Fishstocks, i.e., east coast New Zealand (QMAs 1–4), Stewart-Snares shelf and Campbell Plateau (QMAs 5 and 6), and west coast New Zealand (QMAs 7, 8, and 9). Areas of narrow continental shelf separate these QMA groupings, so they could well provide barriers to stock mixing, particularly for the pale ghost shark. The deep water separating the Bounty Platform from the Campbell Plateau may also provide a barrier to mixing, and these areas may hold separate stocks.

### 4. STOCK ASSESSMENT

No assessment of any stocks of ghost shark has been completed. Therefore, no estimates of yield are available.

#### (a) Estimates of fishery parameters and abundance

Estimates of fishery parameters are not available for ghost sharks. Several time series of relative biomass estimates are available from trawl surveys (Table 5), but wide fluctuations between years suggest the need for caution in using these as indicators of relative abundance.

In 2004, the Plenary agreed that the trawl survey series for both GSP 1 and GSP 5 both indicated that previous catch levels have had no impact on the biomass of pale ghost shark, however, the actual level of catch is not known. The recorded catch history for this species is likely to underestimate actual catches. A revised catch history could be reconstructed based on assumptions concerning bycatch rates in the hoki fishery

**Table 5: Biomass indices (t) and coefficients of variation (CV).**

GSP	Area	Vessel	Trip code	Date	Pale ghost shark

		TAN9604	Feb-Mar 1996	190	29.4	

**(b) Biomass estimates**

No biomass estimates are available for ghost shark.

**(c) Estimation of Maximum Constant Yield (MCY)**

Because no estimates of biomass and harvest rates are available, the only possible method of calculating maximum constant yield is  $MCY = cY_{av}$  (Method 4).

However, it was decided that no estimates of MCY would be presented because:

- i.  $M$  (and hence, the natural variability factor  $c$ ) is unknown,
- ii. the level of discarding is unknown and may have been considerable, and
- iii. no sufficiently long period of catches was available where there were no systematic changes in catch or effort (noting that the period of catches from which  $Y_{av}$  is derived should be at least half the exploited life span of the fish).

**(d) Estimation of Current Annual Yield (CAY)**

In the absence of estimates of current biomass, CAY has not been estimated.

**(e) Other yield estimates and stock assessment results**

No other yield estimates are available.

**(f) Other factors**

Elasmobranchs are believed to have a strong stock-recruit relationship; the number of young born is related directly to the number of adult females. Ghost shark fecundity is unknown, but is probably low. Assuming a strong stock-recruit relationship, Francis & Francis (1992) showed that the estimates of MCY obtained using the equations in current use in New Zealand stock assessments were overly optimistic for rig, and it is likely that they are also unsuitable for ghost sharks.

## 5. STATUS OF THE STOCKS

No estimates of current and reference biomass are available for pale ghost shark.

For all Fishstocks it is not known if recent catch levels are sustainable or at levels that will allow the stocks to move towards a size that will support the MSY. TACCs were increased from 1 October 2004, in GSP 1 and GSP 5, to the level of recent catches. However catches have since declined to well below these levels. Information from trawl surveys indicates that recent catch levels have had no impact on the biomass and there is good recruitment of small pale ghost sharks on the Chatham Rise and in the sub-Antarctic area.

TACCs and reported landings for the 2005/06 fishing year are summarised in Table 6.

**Table 6: Summary of TACCs (t) and reported landings (t) of pale ghost shark for the most recent fishing year.**

Fishstock	QMA	2005–06	2005–06	
		Actual TACC	Estimated landings	
GSP 1	Auckland (East), Central (East) South-East (Coast) (Chatham), Kermadec	1, 2, 3, 4, 10	1150	565
GSP 5	Southland, Sub-antarctic	5, 6	454	134
GSP 7	Challenger, Central (West), Auckland (West)	7, 8, 9	176	9
Total			1780	708
